The β-numeration, born with the works of Rényi and Parry, provides a generalization of the notions of integers, decimal numbers and rational numbers by expanding real numbers in base β, where $\beta > 1$ is not an integer. One of the main differences with the case of numeration in integral base is that the sets which play the role of integers, decimal numbers and rational numbers in base β are not stable under addition or multiplication. In particular, a fractional part may appear when one adds or multiplies two integers in base β. When β is a Pisot number, which corresponds to the most studied case, the lengths of the finite fractional parts that may appear when one adds or multiplies two integers in base β are bounded by constants which only depend on β.

We prove that, for any Perron number β, the set of finite or ultimately periodic fractional parts of the sum, or the product, of two integers in base β is finite. Additionally, we prove that it is possible to compute this set for the case of addition when β is a Parry number. As a consequence, we deduce that, when β is a Perron number, there exist bounds, which only depend on β, for the lengths of the finite fractional parts that may appear when one adds or multiplies two integers in base β. Moreover, when β is a Parry number, the bound associated with the case of addition can be explicitly computed.

Keywords: β-numeration, β-integers, arithmetic automaton, quasicrystals.

Contents

1 Introduction

The β-numeration, born in the late 50's with the works of Renyi [39] and Parry [35], is a generalization of numeration in a non-integer base which enables a modelling of quasicrystals [43]. The number systems defined by the β-numeration are also closely related to canonical number systems [6, 40, 5], number systems generated by iterated function systems [45] or by substitutive systems of Pisot type [20]. A common feature between these fields is the property of self-similarity, which yields results in number theory [7], geometry [29], topology [8, 19], dynamical systems [46, 37, 38], combinatorics on words [22] and theoretical computer science [9]. We focus with this article on applications in computer arithmetics.

Let $\beta > 1$ be an algebraic integer, with $\beta \notin \mathbb{N}$. In the same way as in the case of integral bases, it is possible to expand $x \in [0,1]$ as $x = \sum_{i \in \mathbb{N}^*} u_i \beta^{-i}$, where the sequence $(u_i)_{i \in \mathbb{N}^*}$, called *expansion of x in base β*, takes values in the alphabet $\mathcal{A}_\beta = \{0, \ldots, \lfloor \beta \rfloor\}$. Among the expansions of x in base β, the greatest for the lexicographic order is called *β-expansion of x*, and denoted by $d_\beta(x)$. This expansion can be computed by the *greedy algorithm*, that is, $d_\beta(x) = 0.u_1 \ldots u_n \ldots$, with for all $i \in \mathbb{N}^*$, $u_i = \lfloor \beta T_\beta^{k-1}(x) \rfloor$, where $T_\beta : [0,1] \longrightarrow [0,1[,\ x \longmapsto \{\beta x\}$. The notion of β-expansion was historically introduced by Rényi in [39]. Parry produced in [35] many interesting results concerning the β-numeration, creating and studying among others the dynamical system $([0,1], T_\beta)$ associated with this numeration system. Note that d_β may be extended to positive real numbers by shifting $i+1$ times the β-expansion of $x\beta^{-(i+1)}$, where $x > 1$ and $i \in \mathbb{N}$ is such that $x\beta^{-(i+1)} \in [0,1[$. The map d_β is increasing if $\mathcal{A}_\beta^{\mathbb{Z}}$ is endowed with the lexicographical order [31]. Note that the definition of β-expansion may be extended to negative real numbers as well, by introducing a minus sign, that is, $d_\beta(x) = -d_\beta(-x)$ for any $x \in \mathbb{R}_-^*$.

When $d_\beta(1)$ is either finite or ultimately periodic, β is said to be a *Parry* number. As we see in the following, Parry numbers satisfy particular arithmetic properties.

Remark 1.1. *For any $\beta > 1$, a natural expansion of 1 in base β is 1. However, defining $d_\beta(1)$ as the sequence computed by the greedy algorithm provides useful informations on β. This is why $d_\beta(1)$ is not defined as 1; in particular, $d_\beta(1)$ has a non-empty fractional part.*

Another interesting expansion of 1 in base β is the greatest sequence for the lexicographical order among those which are infinite, that is, they do not end with 0's. This expansion, denoted by $d_\beta^*(1)$, is an improper expansion of 1 in base β; actually, $d_\beta^*(1) = d_\beta(1)$ when $d_\beta(1)$ is not finite. At the opposite of the case of numeration in integral base, $d_\beta^*(1)$ plays a key role in the construction and the study of the associated arithmetical language $\mathcal{L}_\beta$, defined as the set of the factors of the sequences $(u_i)_{i \in \mathbb{N}^*} \in \mathcal{A}_\beta^{\mathbb{N}^*}$ which satisfy the *Parry condition* ([35]):

$$\text{for all } k \in \mathbb{N}, (u_{i+k})_{i \in \mathbb{N}^*} <_{lex} d_\beta^*(1).$$

In the following, we say that $(v_i)_{i \in \mathbb{N}^*}$ is *admissible* (with respect to β) if it satisfies the Parry condition. This notion of admissibility is naturally extended to words and two-sided sequences.

Let $x > 1$. There exists $n \in \mathbb{N}$ such that $d_\beta(x) = u_{-n} \ldots u_0.u_1 \ldots$; the numbers $\sum_{i=0}^{n} u_{-i}\beta^i$ and $\sum_{i \in \mathbb{N}^*} u_i \beta^{-i}$ are respectively called *β-integer part of x*, denoted by $\lfloor x \rfloor_\beta$, and *β-fractional part of x*, denoted by $\{x\}_\beta = x - \lfloor x \rfloor_\beta$. This allows the following generalization for the definition of integers in base β.

Definition 1.2. *We define the set of non-negative β-integers, denoted by $\mathbb{Z}_\beta^+$, as the set of real numbers $x \geq 0$ such that $x = \lfloor x \rfloor_\beta$. We define the set of β-integers as $\mathbb{Z}_\beta = \pm\mathbb{Z}_\beta^+$.*

The following sets generalize the framework of numeration systems with a non-integral base. They play respectively the role of decimal numbers and rational numbers in base β.

Definition 1.3. *We denote by Fin(β) the set of real numbers whose β-fractional part is finite, that is,*

$$\mathit{Fin}(\beta) = \{x \in \mathbb{R}; d_\beta(x) \text{ is finite}\}.$$

We denote by Per(β) the set of real numbers whose β-fractional part is ultimately periodic, that is,

$$\mathit{Per}(\beta) = \{x \in \mathbb{R}; d_\beta(x) \text{ is ultimately periodic}\}.$$

Remark 1.4. *One has* $\mathit{Fin}(\beta) = \bigcup_{i\in\mathbb{N}} \beta^{-i}\mathbb{Z}_\beta = \bigcup_{i\in\mathbb{Z}} \beta^{-i}\mathbb{Z}_\beta$.

The sets $\mathbb{Z}_\beta$ and $\mathrm{Fin}(\beta)$ are not stable under usual operations like addition and multiplication. Indeed, one has $\mathrm{Fin}(\beta) \subset \mathbb{Z}[\beta^{-1}]$ and $\mathrm{Per}(\beta) \subset \mathbb{Q}(\beta)$, and the cases of equalities define numeration systems that are well fitted for performing arithmetics. For instance, Bertrand [12] and Schmidt [42] have independently proven that for any Pisot number, one has $\mathrm{Per}(\beta) = \mathbb{Q}(\beta)$.

The relation $\mathrm{Fin}(\beta) = \mathbb{Z}[\beta^{-1}]$, introduced in [24], is known as the *finiteness property*, denoted by $(\mathcal{F})$. Whereas not yet fully characterized, classes of numbers satisfying the finiteness property have already been extensively studied; see for instance [24, 28, 5]. Indeed, the finiteness property provides topologic and geometric properties for the geometrical realization of the associated dynamical system known as the *Rauzy fractal*, defined in Section 2.2. For instance, due to Akiyama [1], the finiteness property implies that 0 is an exclusive inner point of the Rauzy fractal $\mathcal{T}$ under the additional condition that β is a unit. Also, Theorem 3 of the same article provides a characterization of numbers such that $\mathcal{T}$ is arcwise connected.

Example 1.5. *Let β be the golden ratio $\phi = \frac{1+\sqrt{5}}{2}$, as known as the* Fibonacci *number. Since ϕ is the positive root of $X^2 - X - 1$, one has $\phi^{-1} + \phi^{-2} = 1$; $d_\phi(1) = 0.11$, and the set of admissible words consists of words defined on the alphabet $\{0, 1\}$ which do not contain two consecutive occurences of 1.*

The numeration system associated with the Fibonacci number is the most studied non-standard numeration system. Actually, $\frac{1+\sqrt{5}}{2}$ is the only quadratic Pisot number which belongs to $]1, 2[$, hence it defines from an algebraic point of view the simplest case of numeration in a non-integer base. See for instance [31] for a study of the main properties of this numeration system. Since $1 + 1 = 2 = \phi + \phi^{-2}$, one has $d_\phi(2) = 10.01$, hence $\mathbb{Z}_\phi$ is not stable under addition.

Example 1.6. *Let β be the positive root of the polynomial $X^4 - 2X^3 - X - 1$. Then $d_\beta(1) = 0.2011$, with $1, 2 \in \mathbb{Z}_\beta$ and $d_\beta(3) = 10.111(00012)^\infty$, hence the finiteness property does not hold for the associated numeration system.*

In order to perform arithmetics on β-integers, say for instance to compute the addition of two β-integers, one must be able to renormalize expansions in base β of real numbers obtained after adding β-integers. The renormalization step is performed by transducers, see for instance [23]. Another method consists in applying the greedy algorithm to the real number obtained after adding or multiplying β-integers, which produces its β-expansion. However, if the β-expansion of the sum of two β-integers is neither finite nor ultimately periodic, its computation requires an infinite number of steps. The following notations, $L_\oplus$ and $L_\odot$, are introduced in [26]. They represent the maximal possible length of the β-fractional part which may appear when one adds or multiplies two β-integers, in the case where this β-fractional part is finite. For any $x \in \mathrm{Fin}(\beta)$ with $d_\beta(x) = u_{-N} \dots u_0.u_1 \dots u_{N'}$, we define the *$\beta$-integer length* of x as $l_i(x) = N+1$, and the *β-fractional length* of x as $l_f(x) = N'$.

Definition 1.7. *We define $L_\oplus$ as $\min_{n\in\mathbb{N}}\{n; \forall x, y \in \mathbb{Z}_\beta, x + y \in \mathit{Fin}(\beta) \Rightarrow l_f(x + y) \leq n\}$ when this set is not empty, $+\infty$ otherwise.*

We define $L_\odot$ as $\min_{n\in\mathbb{N}}\{n; \forall x, y \in \mathbb{Z}_\beta, xy \in \mathit{Fin}(\beta) \Rightarrow l_f(x + y) \leq n\}$ when this set is not empty, $+\infty$ otherwise.

The computation of $L_\oplus$ and $L_\odot$ gives an idea of the difficulty of performing arithmetics on $\mathbb{Z}_\beta$. Frougny and Solomyak have proven in [24] that $L_\oplus$ and $L_\odot$ are finite when β is a Pisot number. The computation of these values is however not so easy, especially for $L_\odot$. The value of $L_\oplus$ has been computed for quadratic Pisot numbers, in [18] when β is a unit and in [27] for the non-unit case. However, when β is of higher degree, it is a difficult problem to compute the exact value of $L_\oplus$ or $L_\odot$, and even to compute upper and lower bounds for these two constants. Several examples are studied in [9], where a method is described in

order to compute upper bounds of $L_\oplus$ and $L_\odot$ for Pisot numbers satisfying additional algebraic properties. Also, we perform the computation of $L_\oplus$ for several cases of cubic Pisot numbers in [11], where we use algebraic inequalities as well but we do not construct any automaton. Another class of β-numbers is studied in [10], where upper and lower bounds for $L_\oplus$ and $L_\odot$ are computed.

The aim of this paper is to define an algorithmic process for the computation of $L_\oplus$ under algebraic conditions on β. More precisely, we have the following result. Let us recall that an algebraic integer β is *hyperbolic* when any of its algebraic conjugates α satisfy $|\alpha| \neq 1$.

Theorem 1.8. *Let β be a hyperbolic Perron number. Then $L_\oplus$ and $L_\odot$ are finite. Furthermore, when β is a Parry number, it is possible to compute explicitly $L_\oplus$.*

As a consequence of Theorem 1.8 we deduce that there exist two finite sets F_0 and G_0 which satisfy:

$$(\mathbb{Z}_\beta + \mathbb{Z}_\beta) \cap \mathrm{Fin}(\beta) \subset (\mathbb{Z}_\beta + F_0) \text{ and } (\mathbb{Z}_\beta \cdot \mathbb{Z}_\beta) \cap \mathrm{Fin}(\beta) \subset (\mathbb{Z}_\beta + G_0), \tag{1}$$

by taking $F_0 = \underset{x,y\in\mathbb{Z}_\beta}{\cup} \{\{x+y\}_\beta\} \cap \mathrm{Fin}(\beta)$ and $G_0 = \underset{x,y\in\mathbb{Z}_\beta}{\cup} \{\{xy\}_\beta\} \cap \mathrm{Fin}(\beta)$. When the finiteness condition $(\mathcal{F})$ holds, (1) implies that there exists a finite set F which satisfies $(\mathbb{Z}_\beta - \mathbb{Z}_\beta) \subset (\mathbb{Z}_\beta + F)$, and which can be explicitly computed.

When $\mathbb{Z}_\beta$ is a Meyer set (see Section 2.1), a method which enables the computation of a minimal finite set F satisfying $(\mathbb{Z}_\beta + \mathbb{Z}_\beta) \subset (\mathbb{Z}_\beta + F)$ is presented in [4], where the problem of recognizing the language constituted by sums or differences of positive β-integers is studied as well. On the other hand, $\mathbb{Z}_\beta$ is not a Meyer set when β is neither a Pisot nor a Salem number ([34]).

Let us observe that there is no reason for the cardinality of the finite sets F_0 and G_0, constructed by the automaton described in Section 2, to be minimal among the sets F and G which satisfy $(\mathbb{Z}_\beta - \mathbb{Z}_\beta) \cap \mathrm{Fin}(\beta) \subset (\mathbb{Z}_\beta + F)$ and $(\mathbb{Z}_\beta \mathbb{Z}_\beta) \cap \mathrm{Fin}(\beta) \subset (\mathbb{Z}_\beta + G)$. Therefore, the study performed in this article does not solve the problem of finding minimal sets satisfying these relations, which is studied in [4]. See also [33, 25] for more details.

This article is structured in the following way. Section 2 gathers definitions and notation that are introduced in the framework of β-numeration. In Section 3, we consider expansions of 0 in base β taking values on a finite alphabet. We prove in Section 3.1 that, when β is a hyperbolic Perron number, one can define a geometrical interpretation of these expansions (Lemma 3.1), and that they satisfy several algebraic relations (Lemma 3.3). In Section 3.2, we construct an automaton $\mathcal{G}$ inspired by the arithmetic automaton defined by Rauzy [38] and studied by Siegel [44]. We prove that $\mathcal{G}$ is finite when β is a hyperbolic Perron number (Lemma 3.5) and that the paths in $\mathcal{G}$ define expansions of 0 in base β (Proposition 3.9). In particular, $\mathcal{G}$ contains the finite and ultimately periodic paths which correspond to the sum of two β-integers (Proposition 3.11).

In Section 4.1, we define an algorithmic process which reduces $\mathcal{G}$. We obtain thereby an automaton $\mathcal{G}_\beta^+$, whose edges are labelled by letters of the alphabet $\mathcal{A}_\beta - \mathcal{A}_\beta - \mathcal{A}_\beta = \{-2\lfloor\beta\rfloor, \ldots, \lfloor\beta\rfloor\}$. We prove in Section 4.3 that any sum $x+y$ of two β-integers can be represented by a path in $\mathcal{G}_\beta^+$, whose labels define an expansion of 0 in base β (Theorem 4.5). Then, we study a connection between the study of paths in $\mathcal{G}_\beta^+$ and the finiteness property in Section 4.2 (Proposition 4.3), and we study the case of multiplication of two β-integers in Section 4.4 (Proposition 4.7). We deduce the finiteness of $L_\oplus$ and $L_\odot$ for any Perron number in Section 4.5 (Theorem 4.9).

Finally, in Section 5, we study several questions related to the finiteness of $L_\oplus$. Section 5.1 deals with formal power series in β that are ultimately periodic. We prove that these formal power series are characterized by paths in $\mathcal{G}'_\beta$, an automaton that we obtain similarly as $\mathcal{G}_\beta^+$ by reverting the sense of the edges. In Section 5.2, we retrieve an algebraic construction that was initially given by Thurston [47] in the framework of automata theory. In Section 5.3, we focus on the particular Tribonacci case: we explicitly construct $\mathcal{G}'_\beta$, which admits $\mathcal{G}_\beta^+$ as a subgraph.

2 Definitions and notation

We mainly refer to [36] and [31] for the notations introduced in the sequel.

2.1 Generalities

The sets $\mathbb{N}$ and $\mathbb{N}^*$ respectively denote the sets of non-negative and positive integers. We denote by $[\![i, j]\!]$ the set of integers k such that $i \leq k \leq j$.

Expansions

We consider in this article sequences taking values in alphabets which consist of integers. For convenience, we identify the notions of expansions $\dots u_0.u_1 \dots$ and sequences $(u_n)_{n\in\mathbb{Z}}$. We may also identify words and sequences that admit only finitely many non-zero entries; in this case, $(u_i)_{i\geq N}$ is said to be *finite*. In particular, since $0 \in \mathcal{A}_\beta$ for any $\beta > 1$, we identify $(u_i)_{i\in E}$ and $(u_i)_{i\in\mathbb{Z}}$ for any $E \subset \mathbb{Z}$, setting the missing terms to 0. For any sequence $(u_i)_{i\in\mathbb{Z}}$, we define u^+ as the right-sided sequence $(u_i)_{i\in\mathbb{N}^*}$.

For any alphabet $\mathcal{A}$, one may define the *shift map* $S : \mathcal{A}^{\mathbb{Z}} \to \mathcal{A}^{\mathbb{Z}}, (u_i)_{i\in\mathbb{Z}} \longmapsto (u_{i+1})_{i\in\mathbb{Z}}$. The shift map may be defined as the corresponding shift action on $\mathcal{A}^{\mathbb{N}^*}$ as well. We say that $(u_i)_{i\geq N}$ is *ultimately periodic* if there exists $n \in \mathbb{Z}$ such that $(S^n(u))^+$ is ultimately periodic.

β-numeration and algebraic numbers

Let β be an algebraic integer of degree d. We denote by $\{\alpha_j\}_{j\in[\![1,r+s]\!]}$ the set of algebraic conjugates which differ from β and have a non-negative imaginary part. There are among them r real numbers and s complex numbers (hence $d - 1 = r + 2s$). For convenience, we set $J = [\![1, r + s]\!]$. Let $z \in \mathbb{C}$ and $j \in J$. We call α_j-expansion of z any admissible sequence $(u_i)_{i\geq -N}$ such that $z = \sum_{i\geq -N} u_i\alpha_j^i$. Note that there exist complex numbers having at least two associated different α_j-expansions.

A *Pisot (resp. Salem, Perron) number* is an algebraic integer $\beta > 1$ such that $\max_{j\in J}|\alpha_j| < 1$ (resp. $\max_{j\in J}|\alpha_j| = 1$, $\max_{j\in J}|\alpha_j| < \beta$). Pisot numbers are Parry numbers [12, 42], and Parry numbers are Perron numbers [21, 30]. Note that this latter result was already proven by Parry in [35] for numbers $\beta > 2$. Despite a deep research on Salem numbers ([15, 16, 17]), it is not yet known whether all Salem numbers are Parry numbers.

It is known that $\{x\}_\beta \in [0, 1[$ for any $\beta > 1$, and for any positive real number x. This implies that the set $\mathbb{Z}_\beta$ is relatively dense, that is, the distance between a real number and the closest β-integer is uniformly bounded. Moreover, $\mathbb{Z}_\beta$ is a discrete subset of $\mathbb{R}$ for any $\beta > 1$, and it is uniformly discrete when β is a Parry number, that is, the difference between two β-integers cannot be arbitrarily small. The set of numbers such that $\mathbb{Z}_\beta$ is uniformly discrete is introduced in [14] as the class of specified subshifts, denoted by C_3. According to Schmeling [41], this class has Hausdorff dimension 1, Lebesgue measure 0, and is dense and meager in $]1, +\infty[$.

The property of having uniformly bounded strings of 0's in $d_\beta(1)$ is equivalent to the uniform discreteness of $\mathbb{Z}_\beta$, and therefore to the fact that $\mathbb{Z}_\beta$ is a *Delone set*, that is, a set which is both uniformly bounded and relatively dense. Any Delone set E for which there exists a finite set F such that $E - E \subset E + F$ is said to be a *Meyer set*. The problem to determine for which algebraic numbers is $\mathbb{Z}_\beta$ a Delone or a Meyer set is not totally solved at the moment; however several significant results are known. For instance, $\mathbb{Z}_\beta$ is a Meyer set when β is a Pisot number ([18]).

It is stated as a conjecture in [48] that, for any Perron number β, the lengths of the strings of consecutives 0's which occur in $d_\beta(1)$ are uniformly bounded. However, we believe thanks to numerical evidence and arguments of Diophantine approximation that there exist Perron numbers such that the orbit of 1 under the map $T_\beta : x \longmapsto \{\beta x\}$ is dense in $[0, 1]$.

Automata and paths

We say that $\mathcal{G} = (V, E)$ is an *automaton* if there exists an alphabet $\mathcal{A}$ such that $E \subset V \times V \times \mathcal{A}$. In this case, V consists of *states*, and E consists of *edges*. Let $e = (s, s', i)$ be an edge. We say that s is the *initial state* of e, that s' is the *terminal state* of e, and that e is *labelled* by i.

We call *finite path* any sequence of edges $(e_i)_{i\in[\![1,n]\!]} = ((s_i, s_{i+1}, u_i))_{i\in[\![1,n]\!]}$ in $\mathcal{G}$, where $n \in \mathbb{N}^*$, and *infinite path* any sequence of edges $(e_i)_{i\in\mathbb{N}^*} = ((s_i, s_{i+1}, u_i))_{i\in\mathbb{N}^*}$ in $\mathcal{G}$. The state s_1 is the *initial state* of these paths. If there exist $n, p \in \mathbb{N}^*$ such that for all $i \geq n, s_i = s_{i+p}$, $(e_i)_{i\in\mathbb{N}^*}$ is said to be *ultimately periodic*. If moreover one may choose $n = 1$, $(e_i)_{i\in\mathbb{N}^*}$ is said to be a *loop*; it may be denoted as the

finite path $((s_i, s_{i+1}, u_i))_{i\in[\![1,n]\!]}$. We say that a ultimately periodic path or a loop is *irreducible* when p is minimal in the corresponding definition.

2.2 Generalized Rauzy fractal

We recall here the notion of generalized Rauzy fractal [37], which will be useful in the construction of the automaton defined in Section 3.2. Rauzy fractals were first introduced by Rauzy in [37, 38], then by Thurston in [47]. They provide a geometrical representation of the dynamical system associated with a substitution. In the framework of numeration, they are called *central tiles* by Akiyama [1, 2, 3].

Let β be a hyperbolic Perron number of degree d, and let $\mu_\beta(X) = X^d - \sum_{i=1}^{d} a_i X^{d-i}$ be the minimal polynomial of β over $\mathbb{Z}$. Let M_β be the companion matrix of μ_β, defined as follows:

$$M_\beta = \begin{pmatrix} a_1 & \dots & \dots & \dots & a_d \\ 1 & 0 & \dots & \dots & 0 \\ 0 & \ddots & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & 1 & 0 \end{pmatrix}.$$

It is possible to describe $\mathbb{R}^d$ as the direct sum of the stable sub-spaces $\{\mathcal{H}_j\}_{j\in J}$ with $\mathcal{D}$, where $\mathcal{H}_j$ is expanding when associated with $|\alpha_j| > 1$, contracting when associated with $|\alpha_j| < 1$, and where $\mathcal{D}$ is the eigenspace associated with β. Note that $\mathcal{H}_j \simeq \mathbb{R}$ when $\alpha_j \in \mathbb{R}$, $\mathcal{H}_j \simeq \mathbb{C}$ otherwise. There exists $\overrightarrow{w} \in \mathcal{D}$ and a base of $\mathcal{H} = \bigoplus_{j\in J} \mathcal{H}_j$ constituted by $r+2s$ complex eigenvectors $(\overrightarrow{v_j})_{j\in[\![1,r+2s]\!]}$, which can be chosen such that the following equalities hold:

$$\overrightarrow{e_1} = \sum_{j=1}^{r+2s} \overrightarrow{v_j} + \overrightarrow{w},$$

$$\forall j \in [\![1,s]\!], \forall i \in [\![1,d]\!], v_{r+j}[i] = \overline{v_{r+s+j}[i]},$$

where $\overrightarrow{e_1}$ denotes the first vector in the canonical basis of $\mathbb{Z}^d$, $v_k[i]$ denotes the i-th coordinate of $\overrightarrow{v_k} \in \mathbb{R}^r \times \mathbb{C}^s$ and $z \longmapsto \overline{z}$ is the standard conjugacy on $\mathbb{C}$. These relations allow us to define the projections $\{\overrightarrow{p_{\mathcal{H}_j}}\}_{j\in J}$ and $\overrightarrow{p_{\mathcal{D}}}$ on each associated subspace along the direct sum of the others, and the coordinates $\{p_{\mathcal{H}_j}\}_{j\in J}$ and $p_{\mathcal{D}}$ which satisfy for all $Y \in \mathbb{R}^d$:

$$\overrightarrow{p_{\mathcal{H}_j}}(Y) = p_{\mathcal{H}_j}(Y)\overrightarrow{v_j} \text{ for all } j \in [\![1,r]\!],$$

$$\overrightarrow{p_{\mathcal{H}_j}}(Y) = p_{\mathcal{H}_j}(Y)\ \mathrm{Re}(\overrightarrow{v_j}) \text{ for all } j \in [\![r+1,r+s]\!].$$

For all $j \in J$, we define τ_j as the field morphism: $\mathbb{Q}(\beta) \to \mathbb{Q}(\alpha_j)$, $\beta \longmapsto \alpha_j$. We denote by τ the map: $\mathbb{Q}(\beta) \to \mathbb{R}^r \times \mathbb{C}^s \simeq \mathbb{R}^{d-1}$, $x \longmapsto (\tau_1(x), \dots, \tau_{r+s}(x))$.

The map $\Phi : \mathcal{A}_\beta^{\mathbb{Z}} \longrightarrow \mathbb{R}^d$ is defined by the following relations, where $u = \dots u_0.u_1 \dots \in \mathcal{A}_\beta^{\mathbb{Z}}$:

$$p_{\mathcal{H}_j}(\Phi(u)) = \sum_{i\in\mathbb{N}} u_{-i}\alpha_j^i \text{ when } |\alpha_j| < 1,$$

$$p_{\mathcal{H}_j}(\Phi(u)) = -\sum_{i\in\mathbb{N}^*} u_i\alpha_j^{-i} \text{ when } |\alpha_j| > 1,$$

$$p_{\mathcal{D}}(\Phi(u)) = -\sum_{i\in\mathbb{N}^*} u_i\beta^{-i}.$$

We explain in Remark 3.2 the reason for the minus sign.

Let $\mathcal{X}_\beta^+$, $\mathcal{X}_\beta^-$ and $\mathcal{X}_\beta$ denote the sets which respectively consist of respectively right-sided, left-sided and two-sided admissible sequences.

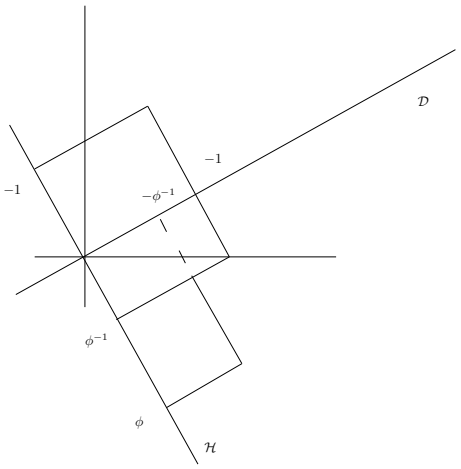

Fig. 1: Generalized Rauzy fractal for the Fibonacci number

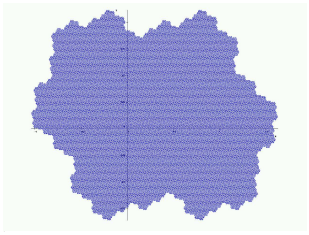

Fig. 2: Rauzy fractal for the Tribonacci number

Remark 2.1. *The notation $\mathcal{X}_\beta$ usually denotes a compact metric space. This is not the case here, since $\mathcal{X}_\beta$ does not contain $0^\infty.d^*_\beta(1)$.*

For any hyperbolic Perron number β, the set $\overline{\bigcup_{u\in\mathcal{X}_\beta}\{\Phi(u)\}}$ is a bounded subset of $\mathbb{R}^d$.

Definition 2.2. *Let β be a hyperbolic Perron number. The set $\overline{\bigcup_{u\in\mathcal{X}_\beta}\{\Phi(u)\}}$, denoted by $\mathcal{R}_\beta$, is called* generalized Rauzy fractal.

Example 2.3. *The generalized Rauzy fractal defined by the Fibonacci numeration is depicted in Figure 1. One has $\mathcal{R}_\beta = [-1,\phi^{-1}]\times[-1,0]\cup[\phi^{-1},\phi]\times[-\phi^{-1},0]$.*

In the particular case where β is a Pisot number, the set $\overline{\bigcup_{u\in\mathcal{X}_\beta^-}\{\Phi(u)\}}$ is a compact set.

Definition 2.4. *Let β be a Pisot number. The set $\mathcal{T}_\beta = \overline{\bigcup_{u\in\mathcal{X}_\beta^-}\{\Phi(u)\}}$ is called* Rauzy fractal *or* central tile.

Note that, for any Pisot number β, $\mathcal{T}_\beta$ is a subset of $\mathcal{H}\simeq\mathbb{R}^{d-1}\simeq\mathbb{R}^r\times\mathbb{C}^s$, whereas $\mathcal{R}_\beta$ is a subset of $\mathbb{R}^d$.

Remark 2.5. *For any Pisot number β, $\mathcal{T}_\beta$ is the projection of $\mathcal{R}_\beta$ on $\bigoplus_{j\in J}\mathcal{H}_j$ along $\mathcal{D}$. Hence $\mathcal{T}_\beta = \overline{\{\tau(\mathbb{Z}^+_\beta)\}}$.*

Example 2.6. *The Rauzy fractal defined by $d_\beta(1)=0.111$, known as the* Tribonacci *fractal, is depicted in Figure 2; $\mathcal{T}_\beta$ is the closure of $\{\sum_{i\in\mathbb{N}}u_i\alpha^i; u_i\in\{0,1\}, u_iu_{i+1}u_{i+2}\neq 111$ for any $i\in\mathbb{N}\}$.*

3 Arithmetic automaton for a hyperbolic Perron number

In this section, we focus on expansions of 0 in base β, that is, sequences $(u_i)_{i\geq N}$ for some $N \in \mathbb{Z}$, taking values in a finite subset of $\mathbb{Z}$, which satisfy

$$\sum_{i\geq N} u_i \beta^{-i} = 0.$$

Let us recall that we may set missing terms to 0, considering that sequences are actually elements of $\mathcal{A}_\beta^{\mathbb{Z}}$.

First, we give in Section 3.1 a geometric representation of two-sided sequences due to Lemma 3.1. Indeed, these representations belong to a bounded subset of $\mathbb{R}^d$ (Lemma 3.3). In Section 3.2, we construct a finite automaton $\mathcal{G}$. We see in Section 3.3 that expansions of 0 in base β defined on $\mathcal{A}_\beta = [\![-2\lfloor\beta\rfloor, \lfloor\beta\rfloor]\!]$ are represented by paths and loops in $\mathcal{G}$.

3.1 Representation of sequences in $\mathbb{R}^d$

From now on, we assume that β is a hyperbolic Perron number, except explicit mention of an opposite hypothesis.

Let x and y be two positive β-integers. We denote by $(u_i)_{i\in\mathbb{Z}}$, $(v_i)_{i\in\mathbb{Z}}$ and $(w_i)_{i\in\mathbb{Z}}$ the respective β-expansions of x, y and $x+y$, setting the value 0 to the missing digits.

Let $\mathcal{X}'_\beta = \{(w_i - u_i - v_i)_{i\in\mathbb{Z}}; (u_i)_{i\in\mathbb{Z}}, (v_i)_{i\in\mathbb{Z}}, (w_i)_{i\in\mathbb{Z}} \in \mathcal{X}_\beta\}$. Let $\mathcal{L}'_\beta$ be the language which consists of factors of elements in $\mathcal{X}'_\beta$. The sequence $(u'_i)_{i\in\mathbb{Z}}$, defined by $u'_i = w_i - u_i - v_i$ for all $i \in \mathbb{Z}$, belongs to $\mathcal{X}'_\beta$. Moreover, $(u'_i)_{i\in\mathbb{Z}}$ is an expansion of 0 in base β defined on the alphabet $\mathcal{A}'_\beta = [\![-2\lfloor\beta\rfloor, \lfloor\beta\rfloor]\!]$, with $u'_i = 0$ for any $i \leq l_i(x+y)$.

We are interested in real numbers having a finite or ultimately periodic β-expansion which are sums of two β-integers. Hence, assume now that $d_\beta(x+y)$ is either finite or ultimately periodic.

If $d_\beta(x+y)$ is finite, then $(u'_i)_{i\in\mathbb{Z}}$ consists of only finitely many non-zeros elements. Hence $\sum_{i\in\mathbb{Z}} u'_i \alpha_j^{-i}$ is defined for all $j \in J$ and equals 0 (since $\tau_j(0) = 0$). We deduce that the following relations hold when $d_\beta(x+y)$ is finite:

$$\sum_{i\in\mathbb{Z}} u'_i \beta^{-i} = 0, \tag{2}$$

$$\sum_{i\in\mathbb{Z}} u'_i \alpha_j^{-i} = 0, \text{ for all } j \in J. \tag{3}$$

If $(u'_i)_{i\in\mathbb{N}^*}$ is ultimately periodic, of preperiod n and of period p, we consider the rational fraction $R(X) = \sum_{i\leq n}^{-l_i(x+y)} u'_i X^{-i} + \frac{X^p}{X^p-1}(\sum_{i=n+1}^{n+p} u'_i X^{-i})$. Clearly, R admits β and any of its algebraic conjugate α_j as roots. Therefore (2) also holds, and we obtain using the rational fraction R a corresponding relation for (3).

Let f_i be the map defined as follows for any $i \in \mathbb{Z}$.

$$f_i : \mathbb{R}^d \to \mathbb{R}^d, X \longmapsto M_\beta X + i\,\overrightarrow{e_1}. \tag{4}$$

Lemma 3.1. *Let $u = (u_i)_{i\in\mathbb{Z}}$ be a two-sided sequence taking values in $\mathcal{A}'_\beta$. Then $\Phi(S(u)) = f_{u_1}(\Phi(u))$.*

Proof. Let us recall that $\mathcal{A}'_\beta$ is the finite alphabet $[\![-2\lfloor\beta\rfloor, \lfloor\beta\rfloor]\!]$, and that S, the shift map naturally defined on $\mathcal{A}_\beta^{\mathbb{N}^*}$, can be defined on any alphabet and extended to two-sided sequences. Let $u = (u_i)_{i\in\mathbb{Z}}$ be a two-sided sequence taking values in $\mathcal{A}'_\beta$. Let $Y_1 = \Phi(u)$. We have the following relations:

$$p_{\mathcal{H}_j}(Y_1) = \sum_{i\in\mathbb{N}} u_{-i}\alpha_j^i \text{ when } \mathcal{H}_j \text{ is contracting,}$$

$$p_{\mathcal{H}_j}(Y_1) = -\sum_{i\in\mathbb{N}^*} u_i \alpha_j^{-i} \text{ when } \mathcal{H}_j \text{ is expanding,}$$

$$p_{\mathcal{D}}(Y_1) = -\sum_{i\in\mathbb{N}^*} u_k \beta^{-i}.$$

Let $Y_2 = \Phi(S(u))$. We get:

$$p_{\mathcal{H}_j}(Y_2) = \sum_{i\in\mathbb{N}} u_{-i+1}\alpha_j^i \text{ when } \mathcal{H}_j \text{ is contracting,}$$

$$p_{\mathcal{H}_j}(Y_2) = -\sum_{i\in\mathbb{N}^*} u_{i+1}\alpha_j^{-i} \text{ when } \mathcal{H}_j \text{ is expanding,}$$

$$p_{\mathcal{D}}(Y_2) = -\sum_{i\in\mathbb{N}^*} u_{i+1}\beta^{-i}.$$

We deduce the following relations between Y_1 and Y_2:

$$p_{\mathcal{H}_j}(Y_2) = g_j(p_{\mathcal{H}_j}(Y_1)),$$

$$p_{\mathcal{D}}(Y_2) = h(p_{\mathcal{D}}(Y_1)),$$

where for any $j \in J$, g_j is the affine map: $\mathbb{C} \longrightarrow \mathbb{C}$, $x \longmapsto \alpha_j x + u_1$, and h the affine map: $\mathbb{C} \longrightarrow \mathbb{C}$, $x \longmapsto \beta x + u_1$. Hence $Y_2 = f_{u_1}(\Phi(u))$, which ends the proof. Note that the alphabet $\mathcal{A}'_\beta$ does not play a particular role, and can be replaced by any finite subset of $\mathbb{Z}$. □

Let us note that, for any $j \in J$, $\mathbb{Z}[\alpha_j]$ is stable under g_j, and that $\mathbb{Z}[\beta]$ is stable under h.

Remark 3.2. *There are two reasons for the minus sign which occurs in the definition of $p_{\mathcal{H}_j}$ when $|\alpha_j| > 1$, and $p_{\mathcal{D}}$, and in the definition of $\mathcal{R}_\beta$ as well. First, if we had defined $p_{\mathcal{H}_j}(\Phi(u)) = \sum_{i\in\mathbb{N}^*} u_i\alpha_j^{-i}$ for any $j \in J$, then the relation between $Y_1 = \Phi(u)$ and $Y_2 = \Phi(S(u))$ would be $p_{\mathcal{H}_j}(Y_2) = \alpha_j p_{\mathcal{H}_j}(Y_1) - u_1$ when $|\alpha_j| > 1$. Hence the relation $\tau_j \circ h = g_j$ would not hold for any $j \in J$, and it would not be possible to define an affine map on $\mathbb{R}^d$ for which Y_2 is the image of Y_1. Secondly, let u be a finite expansion of 0 in base β; one has $\sum_{i\in\mathbb{N}} u_{-i}\beta^i = -\sum_{i\in\mathbb{N}^*} u_i\beta^{-i}$. Since $p_{\mathcal{H}_j}(\Phi(u)) = -\sum_{i\in\mathbb{N}^*} u_i\alpha_j^{-i}$ when $\mathcal{H}_j$ is expanding, we have $p_{\mathcal{H}_j}(\Phi(u)) = \sum_{i\in\mathbb{N}} u_{-i}\alpha_j^i$. Hence we do not have to separate the two cases of expanding or contracting eigenvalues, since $p_{\mathcal{H}_j}(\Phi(u)) = \tau_j(p_{\mathcal{D}}(\Phi(u)))$ for all $j \in J$.*

The following lemma allows us to represent two-sided sequences defined on $\mathcal{A}'_\beta$ as elements which belong to a compact subset of $\mathbb{R}^d$.

Lemma 3.3. *Let $u = (u_i)_{i\in\mathbb{Z}}$ be a two-sided sequence defined on $\mathcal{A}'_\beta$. We then have the following relations:*

$$\text{if } |\alpha_j| > 1, \text{ then } |\sum_{i\in\mathbb{N}^*} u_i\alpha_j^{-i}| \text{ is bounded by } \frac{2\lfloor\beta\rfloor}{|\alpha_j| - 1}, \tag{5}$$

$$\text{if } |\alpha_j| < 1, \text{ then } |\sum_{i\in\mathbb{N}} u_{-i}\alpha_j^{i}| \text{ is bounded by } \frac{2\lfloor\beta\rfloor}{1 - |\alpha_j|}. \tag{6}$$

Proof. First, since $(u_i)_{i\in\mathbb{Z}}$ takes values in the alphabet $\mathcal{A}'_\beta$, we have $|u_i| \leq 2\lfloor\beta\rfloor$ for all $i \in \mathbb{Z}$. If $|\alpha_j| > 1$, then $\sum_{i\in\mathbb{N}^*} u_i\alpha_j^{-i}$ is well defined and satisfies $|\sum_{i\in\mathbb{N}^*} u_i\alpha_j^{-i}| \leq 2\lfloor\beta\rfloor \sum_{i\in\mathbb{N}^*} |\alpha_j|^{-i}$, hence $|\sum_{i\in\mathbb{N}^*} u_i\alpha_j^{-i}| \leq \frac{2\lfloor\beta\rfloor|\alpha_j|^{-1}}{1-|\alpha_j|^{-1}}$. If $|\alpha_j| < 1$, then $\sum_{i\in\mathbb{N}} u_{-i}\alpha_j^i$ satisfies $|\sum_{i\in\mathbb{N}} u_{-i}\alpha_j^i| \leq 2\lfloor\beta\rfloor \sum_{i\in\mathbb{N}} |\alpha_j|^i$. □

Remark 3.4. *Relations that occur in Lemma 3.3 provide inequalities satisfied by images under Φ of sequences defined on $\mathcal{A}'_\beta$. If we are looking for inequalities satisfied by images under Φ of elements of $\mathcal{X}'_\beta$, better upper bounds than those of relations (5) and (6) can be computed since one has actually $\Phi(u) \in \mathcal{R}'_\beta$, where $\mathcal{R}'_\beta = \{z - x - y; x, y, z \in \mathcal{R}_\beta\}$. The use of more accurate inequalities improves the algorithmic process of the construction of the arithmetic graph that we define in Section 3.2; for more details, see [11].*

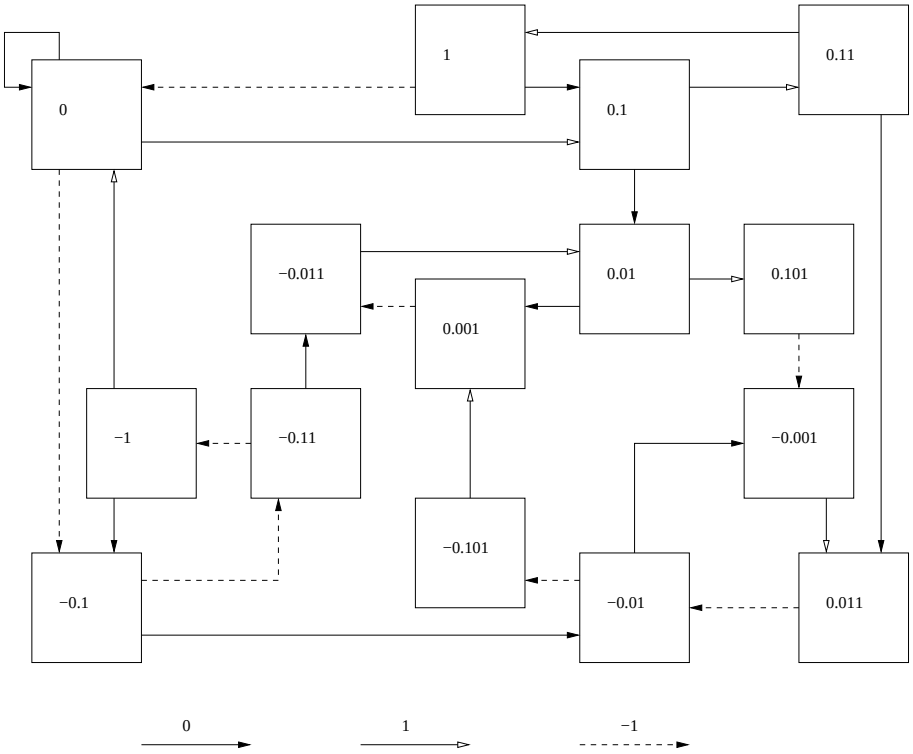

Fig. 3: Arithmetic automaton for the Tribonacci number

3.2 Automaton of expansions of 0 in base β

Under the assumption that β is a hyperbolic Perron number, we will see that it is possible to compute the set of the β-fractional parts of sums of two β-integers, using a slightly modified arithmetic automaton. The notion of *arithmetic automaton* is introduced by Rauzy [38] and studied by Siegel [44]. Roughly speaking, an arithmetic automaton is defined for a unimodular substitution of Pisot type σ. The states of this automaton can be denoted by elements of $\mathbb{Z}[\beta^{-1}]$. Each edge of the automaton represents the action of an affine map, and is labelled by a digit that belongs to the alphabet $[\![-\lfloor\beta\rfloor, \lfloor\beta\rfloor]\!]$, where β is the dominant eigenvalue of M_σ, the incidence matrix of σ. The loops and ultimately periodic paths in this automaton are labelled by expansions of 0 whose letters belong to the alphabet $[\![-\lfloor\beta\rfloor, \lfloor\beta\rfloor]\!]$.

If we add the Parry condition on infinite paths in an arithmetic automaton, we obtain an automaton called *injectivity automaton*. This automaton enables the determination of elements in $\mathbb{R}^{d-1}$ which belong to the fractal boundary of at least two tiles in the periodic tiling of $\mathbb{R}^{d-1}$ defined by $\mathcal{T}_\beta$, in the case where such a tiling exists.

Figure 3 shows the arithmetic automaton for the Tribonacci case, constructed in [32].

Let us see how to adapt the construction of the arithmetic automaton, in order to characterize the β-fractional parts that may appear when one adds two β-integers as paths in an automaton. Starting from $V_0 = \{0\} \subset \mathbb{Z}^d$, we define the sequence $(V_n)_{n\in\mathbb{N}}$ of subsets of $\mathbb{Z}^d$ by the following rule. Let us recall that the maps f_i are defined in (4).

$$\text{For all } n \in \mathbb{N}, V_{n+1} = \Big(\bigcup_{i\in\mathcal{A}'_\beta} f_i(V_n) \cup V_n \Big) \cap \mathcal{R}'_\beta. \tag{7}$$

Lemma 3.5. *The sequence $(V_n)_{n\in\mathbb{N}}$ is stationary.*

Proof. By construction, for any $n \in \mathbb{N}$, V_n is a subset of $\mathbb{Z}^d$ and is included in $\mathcal{R}'_\beta$, which is a bounded subset of $\mathbb{R}^d$. However, $\mathbb{Z}^d \cap \mathcal{R}'_\beta$ is finite as the intersection of a bounded set and a discrete set. Since $(V_n)_{n\in\mathbb{N}}$ is an increasing sequence for the inclusion, there exists $R \in \mathbb{N}$ such that $V_R = V_{R+1}$, hence $V_n = V_R$ for all $n \geq R$. □

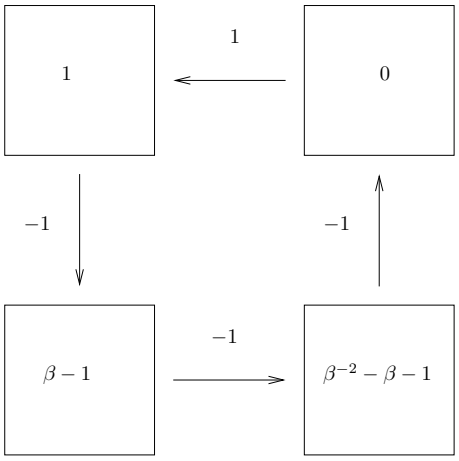

Fig. 4: An example of a loop in $\mathcal{G}$ for the Tribonacci case

Definition 3.6. *We define the automaton of expansions in base β on $\mathcal{A}'_\beta$ as $\mathcal{G} = (V_R, E)$, with $E = V_R \times V_R \times \mathcal{A}'_\beta$, where $(s, s', i) \in E$ if and only if $s' = f_i(s)$.*

Note that, since the restriction of $p_\mathcal{D}$ to $\mathbb{Z}^d$ is one-to-one, the relation $p_\mathcal{D}(s') = \beta p_\mathcal{D}(s) + i$ is equivalent to $s' = M_\beta s + i\overrightarrow{e_1}$ for all states $s, s' \in \mathbb{Z}^d$.

Remark 3.7. *The states in $\mathcal{G}$ are elements of $\mathbb{Z}^d$ which belong to a bounded set defined by relations of Lemma 3.3. We deduce from these relations that $3\prod_{j=1}^{r+s} \frac{2\lfloor\beta\rfloor}{1-|\alpha_j|}$ is an upper bound for N, the number of states in $\mathcal{G}$. Additionally, since $\mathcal{G}$ is deterministic by construction, and since the labels of E take values in $[\![-2\lfloor\beta\rfloor, \lfloor\beta\rfloor]\!]$, the number of edges in $\mathcal{G}$ is less than $(3\lfloor\beta\rfloor + 1)N$. See [4] for remarks concerning the order of growth of N.*

Now, let us see the connection between β-fractional parts, either finite or ultimately periodic, that occur as the sum of two β-integers, and expansions of 0 defined on the alphabet $\mathcal{A}_\beta = [\![-2\lfloor\beta\rfloor, \lfloor\beta\rfloor]\!]$ which are either finite or ultimately periodic.

3.3 Ultimately periodic paths and loops

Proposition 3.8. *Let $n \in \mathbb{N}^*$. Let $((s_i, s_{i+1}, u_i))_{i\in[\![1,n]\!]}$ be a finite path in $\mathcal{G}$. Then, one has $p_\mathcal{D}(s_{n+1}) = \beta^n p_\mathcal{D}(s_1) + \sum_{i=1}^{n} u_i \beta^{n-i}$.*

Proof. By construction, for any $i \in [\![1, n]\!]$, (s_i, s_{i+1}, u_i) is an edge in $\mathcal{G}$ if and only if $s_{i+1} = f_{u_i}(s_i)$. Hence, $s_{i+1} = f_{u_n} \circ \ldots \circ f_{u_1}(s_1)$, and we get:

$$s_{n+1} = M_\beta^n s_1 + \sum_{i=1}^{n} u_i M_\beta^{n-i} \overrightarrow{e_1}. \tag{8}$$

Since for all $i \in [\![1, n]\!]$, $u_i M_\beta^{n-i} \in M_d(\mathbb{Z})$, and since the restriction of $p_\mathcal{D}$ to $\mathbb{Z}^d$ is one-to-one, this relation is equivalent to: $p_\mathcal{D}(s_{n+1}) = \beta^n p_\mathcal{D}(s_1) + \sum_{i=1}^{n} u_i \beta^{n-i}$. □

Let us recall that, by construction of V_R, any state s in $\mathcal{G}$ may be obtained as the image of 0 under the composition of finitely many maps $(f_i)_{i\in\mathcal{A}'_\beta}$. Hence, as a particular case of Proposition 3.8, if the state $\{s\} \in V_R$ is obtained as the image of the state $\{0\}$ under the action of $f_{u_n} \circ \ldots \circ f_{u_1}$, one has $p_\mathcal{D}(s) = \sum_{i=1}^{n} u_i \beta^{n-i}$.

We make the connection between the search of expansions of 0 in base β and the determination of loops or ultimately periodic paths in $\mathcal{G}$ thanks to Propositions 3.9 and 3.11.

Proposition 3.9. *Let $((s_i, s_{i+1}, u_i))_{i\in\mathbb{N}^*}$ be an infinite path in $\mathcal{G}$. Then $(-u_i)_{i\in\mathbb{N}^*}$ is an expansion of $p_{\mathcal{D}}(s_1)$ in base β.*

Proof. Let $((s_i, s_{i+1}, u_i))_{i\in\mathbb{N}^*}$ be an infinite path in $\mathcal{G}$. According to Proposition 3.8, one has for any $n \in \mathbb{N}^*$:

$$p_{\mathcal{D}}(s_1) = \beta^{-n} p_{\mathcal{D}}(s_{n+1}) - \sum_{i=1}^{n} u_i \beta^{-i}.$$

Since $\mathcal{G}$ admits only finitely many states, there exists $N > 0$ such that $|p_{\mathcal{D}}(s)| < N$ for any state s. Hence $|\sum_{i=1}^{n} u_i\beta^{-i}| < N\beta^{-n}$ for any $n \in \mathbb{N}^*$ and $p_{\mathcal{D}}(s_1) = \lim_{n\to+\infty} \sum_{i=1}^{n} (-u_i)\beta^{-i}$, that is, $(-u_i)_{i\in\mathbb{N}^*}$ is an expansion of $p_{\mathcal{D}}(s)$ in base β. □

As a particular case, we obtain the following corollary.

Corollary 3.10. *For any state s_1 in $\mathcal{G}$, there exists at most an infinite path $((s_i, s_{i+1}, u_i))_{i\in\mathbb{N}^*}$ in $\mathcal{G}$ such that $(u_i)_{i\in\mathbb{N}^*}$ is admissible.*

Proof. Let $s_1 = s'_1$ be a state in $\mathcal{G}$. Suppose that there exist two distinct infinite paths $((s_i, s_{i+1}, u_i))_{i\in\mathbb{N}^*}$ and $((s'_i, s'_{i+1}, v_i))_{i\in\mathbb{N}^*}$ in $\mathcal{G}$, such that $(u_i)_{i\in\mathbb{N}^*}$ and $(v_i)_{i\in\mathbb{N}^*}$ are admissible. Since these infinite paths are distincts, there exists $n \in \mathbb{N}$ such that $s_n = s'_n$ and $s_{n+1} \neq s'_{n+1}$, hence $u_n \neq v_n$. Due to Proposition 3.9, one has $p_{\mathcal{D}}(-s_1) = \sum_{i\in\mathbb{N}^*} u_i\beta^{-i} = \sum_{i\in\mathbb{N}^*} v_i\beta^{-i}$, that is, $(u_i)_{i\in\mathbb{N}^*}$ and $(v_i)_{i\in\mathbb{N}^*}$ are distincts β-expansions of $p_{\mathcal{D}}(-s_1)$, which is absurd. □

The study of ultimately periodic paths and loops which occur in $\mathcal{G}$ allows us to determine the finite and ultimately periodic expansions of 0 in base β on $\mathcal{A}'_\beta$, thanks to the following proposition. Let us remind that, for $x \in \mathrm{Fin}(\beta)$ with $d_\beta(x) = u_{-N} \dots u_0.u_1 \dots u_N$, $l_i(x)$ and $l_f(x)$ respectively denote the lengths of the β-integer part and the length of the β-fractional part of x, that is, $l_i(x) = N + 1$ and $l_f(x) = M$.

Proposition 3.11. *Let $x, y \in \mathbb{Z}^+_\beta$. Set $N = l_i(x+y)$ and $N' = l_f(x+y)$. Let $(u_i)_{i\in\mathbb{Z}}$, $(v_i)_{i\in\mathbb{Z}}$ and $(w_i)_{i\in\mathbb{Z}}$ be respectively the β-expansions of x, y and $x + y$. Let $(u'_i)_{i\in\mathbb{Z}}$ be defined by $u'_{i+l_i(x+y)} = w_i - u_i - v_i$ for all $i \in \mathbb{Z}$. Then $(u'_i)_{i\in\mathbb{Z}}$ labels a path in $\mathcal{G}$ starting from the state $\{0\}$. Moreover, if $x + y \in$ Per(β), this path is ultimately periodic; if $x + y \in$ Fin(β), this path may be represented by a loop.*

Proof. Let $x, y \in \mathbb{Z}^+_\beta$. Set $N = l_i(x + y)$ and $N' = l_f(x + y)$. Let $(u_i)_{i\in\mathbb{Z}}$, $(v_i)_{i\in\mathbb{Z}}$ and $(w_i)_{i\in\mathbb{Z}}$ be respectively the β-expansions of x, y and $x + y$. Let $(u'_i)_{i\in\mathbb{Z}}$ be defined by $u'_{i+l_i(x+y)} = w_i - u_i - v_i$ for all $i \in \mathbb{Z}$. Since the β-expansions of x and y are finite, and since $x+y \geq \max(x, y)$, one has $u'_i = u_i + v_i$ for any $i \leq -l_i(x + y)$. As a consequence, the left-sided part of u' consists of zeros, that is, $\Phi(S^{-k}(u')) = 0$ for any $k \in \mathbb{N}$; due to Proposition 3.9, $(u'_i)_{i\in\mathbb{N}^*}$ is an expansion of 0 in base β. Therefore we can assume that expansions of 0 are represented in the automaton $\mathcal{G}$ by paths whose starting point is the fixed point of f_0, that is, the state $\{0\}$.

Since the restriction of $p_{\mathcal{D}}$ to $\mathbb{Z}^d$ is one-to-one, there exists a sequence $(s_i)_{i\in\mathbb{N}^*}$ of elements in $\mathbb{Z}^d$ such that, for any $i \geq 2$, s_i is obtained as the image of $s_1 = \{0\}$ under the maps $f_{u'_{i-N-1}} \circ \dots \circ f_{u'_{1-N}}$. Due to Lemma 3.1, one has $\Phi(S^i(u')) = f_{u'_{i-N-1}} \circ \dots \circ f_{u'_{1-N}}(\Phi(u'))$ for any $i \in \mathbb{N}$. Hence, by construction of V_R, $(s_i)_{i\in\mathbb{N}^*}$ consists of states in $\mathcal{G}$.

Clearly, if $x + y \in \mathrm{Per}(\beta)$, then $(u'_i)_{i\in\mathbb{Z}}$ is ultimately periodic. If $x + y \in \mathrm{Fin}(\beta)$, one has $u'_k = 0$ for any $k \geq l_f(x+y)+1$, hence $s_k = 0$ for any $k \geq 2+l_i(x+y)+l_f(x+y)$, and we obtain a loop of length $1 + l_i(x + y) + l_f(x + y)$. □

4 Finiteness of ultimately periodic β-fractional parts for sums or products of two β-integers

The automaton $\mathcal{G}$ previously constructed contains states and edges that are not used in order to characterize expansions of 0 in base β that are neither finite nor ultimately periodic. Therefore we define in Section 4.1 an algorithmic method of reduction for $\mathcal{G}$. Actually, this method is not needed in our study, but it may improve in a significant way the algorithmic construction of β-fractional parts of sums of β-integers. In Section 4.2, we make a connection between the finiteness property and the property of connectedness for

$\mathcal{G}_\beta^+$. Then, we consider the case of the addition of two positive β-integers in Section 4.3, and the case of the product of two β-integers in Section 4.4. Finally, we prove in Section 4.5 the finiteness of $L_\oplus$ and $L_\odot$.

4.1 Reduction of $\mathcal{G}$

Due to Proposition 3.11, expansions of finite or ultimately periodic β-fractional parts of the sum of two β-integers label loops and ultimately periodic paths in $\mathcal{G}$. However, we are only interested in loops and ultimately periodic paths which are labelled by sequences in $\mathcal{X}'_\beta$. Indeed, only these sequences may provide expansions in base β on the alphabet $\mathcal{A}'_\beta$, constructed digit by digit, for $z-x-y$, with $x, y \in \mathrm{Fin}(\beta)$ and $z \in \mathrm{Per}(\beta)$. The algorithm $\mathcal{G}$ defined in Section 3.2 may compute an automaton with useless states and edges, in the sense that $\mathcal{G}$ may contain states and edges that are not used by any loop or ultimately periodic path which starts from $\{0\}$. Let us see how to prune $\mathcal{G}$.

First, we remove recursively the states of $\mathcal{G}$ which are not the initial state of any edge, and the edges which admit those removed states as terminal state. This rule removes recursively the states of $\mathcal{G}$ which are never reached by an infinite path starting from the state $\{0\}$. We obtain at this point $\mathcal{G}_0$, the connected component of $\mathcal{G}$ which contains the state $\{0\}$. We denote by $(\mathcal{R}_1)$ the rule which consists in extracting the connected component of a subgraph of $\mathcal{G}$ which contains $\{0\}$.

We do not have used any admissibility condition in the construction of $\mathcal{G}$ so far. Therefore we need now to define a computational rule in order to remove the states and the edges that are only used by ultimately periodic paths or loops which are not labelled by elements of $\mathcal{L}'_\beta$, the language of factors of elements in $\mathcal{X}'_\beta$. Bertrand has proven in [13] that β is a Parry number if and only if $\mathcal{L}_\beta$ is recognizable by a finite automaton. In this case, $\mathcal{L}'_\beta$ is recognizable by the triple cartesian product automaton which recognizes $\mathcal{L}_\beta$, and it is possible to determine whether a ultimately periodic path or a loop in $\mathcal{G}_0$ belong to $\mathcal{L}'_\beta$. When β is a hyperbolic Perron number that is not a Parry number, we cannot recognize $\mathcal{L}'_\beta$ by a finite automaton. In this case, it is not possible to compute effectively the ultimately periodic paths in $\mathcal{G}_0$.

The rule which consists of removing edges and states that are not elements of any loop or ultimately periodic path labelled by a sequence of $\mathcal{L}'_\beta$, that we denote by $(\mathcal{R}_2)$, can be performed by an algorithmic process when β is a Parry number. The graph $\mathcal{G}_1$ that we obtain after having applied $(\mathcal{R}_2)$ to $\mathcal{G}_0$ is connected, since for any edge (s, s', i) of $\mathcal{G}_1$, there exists a ultimately periodic path or a loop which contains (s, s', i).

Definition 4.1. *We define $\mathcal{G}_\beta^+$ as the connected component of $\mathcal{G}$ containing $\{0\}$, such that, for any edge (s, s', l), there exist an infinite path $((s_i, s_{i+1}, u_i))_{i\in\mathbb{N}}$ in $\mathcal{G}$ and $i \in \mathbb{N}^*$ such that $(s, s', l) = (s_i, s_{i+1}, u_i)$.*

Note that if we want to consider only finite expansions of 0 in base β, we have to consider the strongly connected component, instead of the connected component, of $\mathcal{G}_\beta^+$ which contains $\{0\}$, and whose loops are labelled by elements of $\mathcal{L}'_\beta$.

Remark 4.2. *In order to construct the reduced automaton $\mathcal{G}_\beta^+$, we can commute the order of application of the rules $(\mathcal{R}_2)$ and $(\mathcal{R}_1)$ to $\mathcal{G}$. However, since the admissibility condition associated with $\mathcal{L}'_\beta$ is difficult to compute, it is more convenient from a practical point of view to perform first $(\mathcal{R}_1)$.*

4.2 Connection with the finiteness property

Let us see a connection between the connectedness of $\mathcal{G}_\beta^+$ and the $(\mathcal{F})$ property. The following proposition provides a sufficient condition for having the finiteness property $(\mathcal{F})$ not satisfied, that is, $\mathrm{Fin}(\beta) \neq \mathbb{Z}[\beta^{-1}]$. We recall that several comments concerning $(\mathcal{F})$ are given in the introduction.

Proposition 4.3. *If there exist a non trivial ultimately periodic path $((s_i, s_{i+1}, w'_i))_{i\in\mathbb{N}^*}$ in $\mathcal{G}_\beta^+$ such that $(w'_i)_{i\in\mathbb{N}^*} \in \mathcal{X}'^+_\beta$, and $N \in \mathbb{N}$ such that $(w'_{i+N})_{i\in\mathbb{N}^*} \in \mathcal{X}_\beta^+$, then property $(\mathcal{F})$ does not hold.*

Proof. Let $((s_i, s_{i+1}, u'_i))_{i\in\mathbb{N}^*}$ be a ultimately periodic path in $\mathcal{G}_\beta^+$, such that $(u'_i)_{i\in\mathbb{N}^*} \in \mathcal{X}'^+_\beta$. Assume that there exists $N \in \mathbb{N}$ such that $(u'_{i+N})_{i\in\mathbb{N}^*} \in \mathcal{X}_\beta^+$. Since $(u'_i)_{i\in\mathbb{N}^*}$ belongs to $\mathcal{X}'^+_\beta$, there exist $(u_i)_{i\in\mathbb{N}^*}$, $(v_i)_{i\in\mathbb{N}^*}$ and $(w_i)_{i\in\mathbb{N}^*} \in \mathcal{X}_\beta^+$ such that $\forall i \in \mathbb{N}^*$, $u'_i = w_i - u_i - v_i$. Let x, y and z be the real numbers such that $d_\beta(x) = (u_i)_{i\in\mathbb{N}^*}$, $d_\beta(y) = (v_i)_{i\in\mathbb{N}^*}$ and $d_\beta(z) = (w_i)_{i\in\mathbb{N}^*}$. By hypothesis, $(u'_{i+N})_{i\in\mathbb{N}^*} \in \mathcal{X}_\beta^+$. Hence one may set $u'_i = w_i$ and $u_i = v_i = 0$ for any $i \geq N$; the β-expansions of x and y are then finite,

and $x' = \beta^N x$ and $y' = \beta^N y$ belong to $\mathbb{Z}_\beta^+$. Since $d_\beta(x'+y') = (u'_{i+N})_{i\in\mathbb{N}^*} \in \mathcal{X}_\beta^+$ is ultimately periodic by hypothesis, either the sequence $(u'_{i+N})_{i\in\mathbb{N}^*}$ consists of 0, or one has $x'+y' \notin \mathrm{Fin}(\beta)$. □

Note that the assumption of Proposition 4.3 implies that $\mathcal{G}_\beta^+$ is a connected graph, however we do not know whether $\mathcal{G}_\beta^+$ is strongly connected. Actually, if $\mathcal{G}_\beta^+$ is a strongly connected graph, then for any state $\{s\}$ there exists $k \in \mathbb{N}^*$ and a loop $((s_i, s_{i+1}, u_i))_{i\in[\![1,k]\!]}$ which starts from $\{0\}$ in $\mathcal{G}$ such that $s_i = s$. Since $(u_i)_{i\in\mathbb{N}^*}$ is a finite expansion of 0 in base β, we deduce $p_{\mathcal{D}}(s) \in \mathrm{Fin}(\beta)$.

There could exist β such that, for any $x, y \in \mathbb{Z}_\beta$, the sum $x+y$ either belong to $\mathrm{Fin}(\beta)$ or $\mathbb{Q}(\beta) \setminus \mathrm{Per}(\beta)$, with examples respectively belonging to each of these two sets. However, if β is a Pisot number, $\mathbb{Q}(\beta) \setminus \mathrm{Per}(\beta) = \varnothing$. Hence $(\mathcal{F})$ holds if and only if $\mathcal{G}_\beta^+$ is a strongly connected graph.

4.3 Addition of two positive β-integers

Proposition 4.4. *Let β be a hyperbolic Perron number. Let $z \in [0,1[$ and $(w_i)_{i\in\mathbb{N}^*} = d_\beta(z)$.*

If $z \in \mathrm{Fin}(\beta)$, then there exist $x, y \in \mathbb{Z}_\beta^+$ such that $z = \{x+y\}_\beta$ if and only if there exist a loop $((s_i, s_{i+1}, w'_i))_{i\in[\![1,n]\!]}$ in $\mathcal{G}_\beta^+$ starting from $\{0\}$ and $k \in \mathbb{N}^*$ such that, for all $i \in [\![1,n]\!]$, $w'_{i+k} = w_i$.

If $z \in \mathrm{Per}(\beta)$, then there exist $x, y \in \mathbb{Z}_\beta^+$ such that $z = \{x+y\}_\beta$ if and only if there exist a ultimately periodic path $((s_i, s_{i+1}, w'_i))_{i\in\mathbb{N}^*}$ in $\mathcal{G}_\beta^+$ starting from $\{0\}$, and $k \in \mathbb{N}$ such that for all $i \in \mathbb{N}^*$, $w'_{i+k} = w_i$.

Proof. We reduce the proof to the case where $\{x+y\}_\beta$ is ultimately periodic, since the finite case is a particular subcase and does not require any additional argument. As usual, let $x, y \in \mathbb{Z}_\beta^+$ and $(u_i)_{i\in\mathbb{Z}}$, $(v_i)_{i\in\mathbb{Z}}$, $(w_i)_{i\in\mathbb{Z}}$ denote respectively $d_\beta(x)$, $d_\beta(y)$ and $d_\beta(x+y)$. Let $(u'_i)_{i\in\mathbb{Z}}$ be defined by $u'_i = w_i - u_i - v_i$ for all $i \in \mathbb{Z}$. If $x+y \in \mathrm{Per}(\beta)$, $(u'_i)_{i\in\mathbb{Z}}$ labels a ultimately periodic path starting from $\{0\}$ in $\mathcal{G}_\beta^+$ due to Proposition 3.11.

On the other hand, let $((s_i, s_{i+1}, w'_i))_{i\in\mathbb{N}^*}$ be a path in $\mathcal{G}_\beta^+$ starting from $\{0\}$. Assume that there exists $k \in \mathbb{N}$ such that for all $i \in \mathbb{N}^*, w'_{i+k} = w_i$. Due to Proposition 3.9, $(w'_i)_{i\in\mathbb{N}^*}$ is an expansion of 0 in base β. By construction of $\mathcal{G}_\beta^+$, any factor of $(w'_i)_{i\in\mathbb{N}^*}$ belongs to $\mathcal{L}'_\beta$. As a consequence, there exist three admissible sequences $(u_i)_{i\in\mathbb{Z}}$, $(v_i)_{i\in\mathbb{Z}}$ and $(w_i)_{i\in\mathbb{Z}}$ such that $w'_{i+k} = w_i - u_i - v_i$ for all $i \in \mathbb{Z}$. Moreover, since $w'_{i+k} = w_i$ for all $i \in \mathbb{N}^*$, one has $u_i - v_i = 0$ for all $i \in \mathbb{N}^*$. Since $(u_i)_{i\in\mathbb{Z}}$ and $(v_i)_{i\in\mathbb{Z}}$ take values in $\mathcal{A}_\beta$, which contains only non-negative elements, we get $u_i = v_i = 0$ for all $i \in \mathbb{N}^*$. Hence $(u_i)_{i\in\mathbb{Z}}$ and $(v_i)_{i\in\mathbb{Z}}$ are β-expansions of β-integers x and y, and $(w_i)_{i\in\mathbb{Z}}$ is the β-expansion of $x+y$; since $(w_i)_{i\in\mathbb{N}^*}$ is defined as the β-expansion of z, one gets $z = \{x+y\}_\beta$. □

Theorem 4.5. *Let β be a hyperbolic Perron number. The set $\{d_\beta(x+y)$ finite or ultimately periodic; $x, y \in \mathbb{Z}_\beta^+\}$ is finite. Furthermore, it is possible to compute effectively this set when β is a Parry number.*

Proof. Let $((s_i, s_{i+1}, u_i))_{i\in\mathbb{N}^*}$ be an infinite path in $\mathcal{G}_\beta$. Then, for any $k \in \mathbb{N}^*$, $(-u_{k+i})_{i\in\mathbb{N}}$ is an expansion of s_k in base β as seen in Proposition 3.9.

Due to Corollary 3.10, for any state s_i in $\mathcal{G}'_\beta$, there exists at most one infinite path $((s_k, s_{k+1}, u_k))_{k\geq i}$ in $\mathcal{G}'_\beta$ such that $(u_k)_{k\geq i}$ satisfies the Parry condition. Moreover, since there are only finitely many states in $\mathcal{G}'_\beta$, any path $((s_k, s_{k+1}, u_k))_{k\in\mathbb{N}^*}$ such that $(u_k)_{k\geq i}$ satisfies the Parry condition is ultimately periodic. Hence there are finitely many irreducible ultimately periodic paths in $\mathcal{G}_\beta$ that are labelled by an admissible word. We may check for each of these paths whether the hypothesis introduced in Proposition 4.4 holds. This provides only finitely many possible numbers which can be described as the β-fractional parts of the sum of two positive β-integers.

Suppose additionally that β is a Parry number. Then the automaton which define the admissibility condition is finite; the triple cartesian product of this automaton contains the automaton A' which recognizes expansions $\{(w_i - u_i - v_i)_{i\in\mathbb{Z}}; (u_i)_{i\in\mathbb{Z}}, (v_i)_{i\in\mathbb{Z}}, (w_i)_{i\in\mathbb{Z}} \in \mathcal{X}_\beta\}$. Hence A' is finite; as a consequence, one may effectively compute the loops that satisfy the hypothesis of Proposition 4.4. □

In order to compute $L_\oplus$, we have to determine as well the possible paths which correspond to the subtraction of two positive β-integers x and y, with $x > y$.

Proposition 4.6. *Let β be a hyperbolic Perron number. The set $\{d_\beta(x-y)$ finite or ultimately periodic; $x, y \in Z_\beta^+, x > y\}$ is finite. Furthermore, it is possible to compute effectively this set when β is a Parry number.*

Proof. Let us see that the case of subtraction of two non-negative β-integers is essentially the same case as the addition, and does not require additional ideas. Let $x, y \in \mathbb{Z}_\beta^+$, with $x > y$. Let $z = x - y$, and let

$(u_i)_{i\in\mathbb{Z}}$, $(v_i)_{i\in\mathbb{Z}}$ and $(w_i)_{i\in\mathbb{Z}}$ be the respective β-expansions of x, y and z. Then $(w_i+v_i-u_i)_{i\in\mathbb{Z}}$ is an expansion of 0 in base β, and $(w_i)_{i\in\mathbb{N}^*}=d_\beta(\{x-y\}_\beta)$.

Actually, we have to replace $\mathcal{A}'_\beta$ by $[\![-\lfloor\beta\rfloor,2\lfloor\beta\rfloor]\!]$ in (7) to obtain a sequence of finite sets $(V'_i)_{i\in\mathbb{N}^*}$, which is increasing for the inclusion and stationary as well. We construct then an automaton, where V'_R are the states and the edges (s,s',i) corresponds to $s'=f_i(s)$ whenever $i\in[\![-\lfloor\beta\rfloor,2\lfloor\beta\rfloor]\!]$. Easily, we obtain similar versions for Propositions 3.8, 3.9, 3.11 and 4.4. □

4.4 Multiplication of two β-integers

We study in this subsection the β-fractional parts of the product of two β-integers.

Proposition 4.7. *Let β be a hyperbolic Perron number. Then the set of finite or ultimately periodic β-fractional parts of the product of two β-integers is finite.*

Proof. We may suppose without loss of generality that $x,y\in\mathbb{Z}_\beta^+$. Let $d_\beta(x)=(u_i)_{i\in\mathbb{Z}}$, $d_\beta(y)=(v_i)_{i\in\mathbb{Z}}$ and $d_\beta(xy)=(w_i)_{i\in\mathbb{Z}}$. Suppose moreover that $d_\beta(xy)$ is either finite or ultimately periodic. We have for any $j\in J$ the relation:

$$\sum_{k\in\mathbb{Z}}(w_k-w'_k)\alpha_j^{-k}=0,$$

where the sequence $(w'_k)_{k\in\mathbb{Z}}$ is defined by $w'_{-k}=\sum_{i=0}^{k}u_{-i}v_{i-k}$ if $k\in\mathbb{N}$, $w'_k=0$ otherwise.

Note that, unlike the case of addition, the sequence $(w'_i)_{i\in\mathbb{Z}}$ does not take values on a finite alphabet. However, since $(u_i)_{i\in\mathbb{Z}}$ and $(v_i)_{i\in\mathbb{Z}}$ take values in $\mathcal{A}_\beta$, we have $w'_{-i}\in[\![0,(i+1)\lfloor\beta\rfloor^2]\!]$ for all $i\in\mathbb{N}$. This means that, for any α_j an algebraic conjugate of β such that $|\alpha_j|>1$, the series $\sum_{i\in\mathbb{N}}w'_{-i}\alpha_j^i$ is absolutely convergent, since the main term of this series is bounded in modulus by the product of a polynomial term and a geometric term of modulus less than 1. Hence for all $j\in J$, there exists $B_j\in\mathbb{R}_+^*$ such that $\sum_{i\in\mathbb{N}}\nu_{-i}|\alpha_j|^i<B_j$.

We retrieve an equation which provides a connection between the β-integer part and the β-fractional part of xy, which is

$$\sum_{i\in\mathbb{N}}(w_{-i}-w'_{-i})M_\beta^i\overrightarrow{e_1}=-\sum_{i\in\mathbb{N}^*}w_iM_\beta^{-i}\overrightarrow{e_1}. \tag{9}$$

Since $(w_{-i})_{i\in\mathbb{N}}$ and $(w'_{-i})_{i\in\mathbb{N}}$ contain finitely many non-zero elements, the right hand side of (9) belongs to $\mathbb{Z}^d$, and we get additionally the following relations:

$$\text{if } |\alpha_j|>1, \text{ then } |\sum_{i\in\mathbb{N}^*}w_i\alpha_j^{-i}|<\frac{|\alpha_j|^{-1}}{|\alpha_j|-1},$$

$$\text{if } |\alpha_j|<1, \text{ then } |\sum_{i\in\mathbb{N}}(w_{-i}-w'_{-i})\alpha_j^i|<B_j+\frac{1}{1-|\alpha_j|}.$$

As in the case of addition, the finite or ultimately periodic β-fractional parts of the product of two β-integers label loops in an automaton with states that belong to the discrete lattice $\mathbb{Z}^d$ and a bounded set $\mathcal{B}\subset\mathbb{R}^d$ defined by the previous inequalities. It follows that there are only finitely many finite β-fractional parts of products of two β-integers. □

Remark 4.8. *As mentioned in the proof, the only noteworthy difference with the case of addition is that it is not possible to compute $\{\{xy\}_\beta;x,y\in\mathbb{Z}_\beta^+\}$ since $(w'_{-i})_{i\in\mathbb{N}}$ may take infinitely many distinct values.*

4.5 Finiteness of $L_\oplus$ and $L_\odot$

In [9], it has been asked whether there exists a Perron number β such that $L_\oplus$ or $L_\odot$ are not finite. The following theorem answers this question.

Theorem 4.9. *Let β be a Perron number. Then $L_\oplus$ and $L_\odot$ are finite. If additionally β is a Parry number, $L_\oplus$ is effectively computable.*

Proof. Let β be a Perron number. If β is hyperbolic, the result is a consequence of Theorem 4.5 and Proposition 4.7.

Now, suppose that β is not hyperbolic, that is, there exists an algebraic conjugate α_j of β such that $|\alpha_j| = 1$. Since $\mu_\beta(\alpha^{-1}) = \mu_\beta(\overline{\alpha_j}) = 0$, μ_β is a reciprocal polynomial, hence $\mu_\beta(\beta^{-1}) = 0$.

First, let us consider the case of the addition of two β-integers. Let us recall that $l_f(x)$ denotes the length of the β-fractional part of $x \in \mathrm{Fin}(\beta)$. Suppose that $L_\oplus$ is not finite. This implies that there exists a countable subset I of $\mathbb{N}^*$ such that, for any $k \in I$, there exist $x, y \in \mathbb{Z}_\beta^+$ such that $l_f(x+y) = k$. Note that, in this case, $l_f(\beta^l(x+y)) = k - l$ for any $l < k$. Hence for any $k \in \mathbb{N}^*$, there exist $x_k, y_k \in \mathbb{Z}_\beta^+$ such that $l_f(x_k + y_k) = k$. We deduce that there exist a sequence $(u^{(n)})_{n\in\mathbb{N}^*}$, with $u^{(n)} = (u_i^{(n)})_{i\in\mathbb{N}^*}$ for all $n \in \mathbb{N}^*$, such that, for any $n \in \mathbb{N}^*$:

1. $(u_i^{(n)})_{i\in\mathbb{Z}} \in \mathcal{X}'_\beta$ and $(u_i^{(n)})_{i\in\mathbb{N}^*} \in \mathcal{X}_\beta^+$,
2. $(u_i^{(n)})_{i\in\mathbb{Z}}$ is a finite expansion of 0 in base β,
3. there exists $x_n > 0$ such that $d_\beta(x_n) = (u_i^{(n)})_{i\in\mathbb{N}^*}$ and $l_f(x_n) = n$.

Let $n \in \mathbb{N}^*$. Since $(u_i^{(n)})_{i\in\mathbb{Z}}$ contains finitely many non-zero digits for any $n \in \mathbb{N}^*$, it defines an expansion of 0 in base β, that is, $\sum_{i\in\mathbb{Z}} u_i^{(n)}\beta^{-i} = 0$. However, β^{-1} is an algebraic conjugate of β, one has $\sum_{i\in\mathbb{Z}} u_i^{(n)}\beta^{i} = 0$ as well, which is equivalent to $\sum_{i\in\mathbb{N}^*} u_i^{(n)}\beta^{i} = \sum_{i\in\mathbb{N}} u_{-i}^{(n)}\beta^{-i}$. Since $l_f(x_n) = n$ implies $u_n^{(n)} \geq 1$, the left-hand side of the previous equality is greater than β^n. On the other hand, since $(u_i^{(n)})_{i\in\mathbb{N}^*}$ takes values in $\mathcal{A}_\beta$, the right-hand side of the equality belongs is bounded, hence a contradiction. We deduce that $L_\oplus$ is finite when β is a non-hyperbolic Perron number.

Assume now that $L_\odot$ is not finite. The only difference with the case of addition is that $(u_i^{(n)})_{i\in\mathbb{Z}}$ does not take values in a finite alphabet. However, using the same argument as in Proposition 4.7, and using the fact that β^{-1} is an algebraic conjugate of β by hypothesis, we obtain the same contradiction as in the case of addition if we suppose that for any $k \in \mathbb{N}^*$, there exist $x, y \in \mathbb{Z}_\beta^+$ such that $l_f(xy) = k$. Hence $L_\odot$ is finite. □

Remark 4.10. *If β is not a Parry number, we do not know whether the algorithmic construction of the set of finite β-fractional parts of the sum of two β-integers terminates.*

5 Other related questions

In Section 5.1, we consider formal power series in β when β is a Pisot number. Since they define converging series when we replace β by any of its algebraic conjugate, we construct in the same way as in Section 4 an automaton $\mathcal{G}'_\beta$, which characterizes formal power series in β whose sequences of coefficients are both admissible and ultimately periodic. Then, in Section 5.2, we give an explicit algebraic construction of Thurston's automaton, introduced at first in [47]. Finally, we construct in Section 5.3 the automaton $\mathcal{G}_\beta$ for the Tribonacci case.

5.1 Formal power series in β

In [11], we studied the computation of $L_\oplus$ in the particular case of Tribonacci. We have proven that the sum of two β-integers has a β-fractional part of length less or equal to 5, and that there exist two elements of the associated Rauzy fractal $\mathcal{T}$ such that their sum admits an α-expansion of length 6. This can be seen as a limit case, in the sense that, for any $z \in \mathcal{T}$, there exists a sequence of β-integers $(b_i)_{i\in\mathbb{N}}$ such that $(z_i)_{i\in\mathbb{N}}$, the sequence of elements in $\mathcal{T}$ which satisfy $p_{\mathcal{H}_j}(z_i) = \tau_j(b_i)$ for all $j \in J$, tends to z. We see here that the study of limit cases is related to the study of formal power series in β whose sequences of coefficients consist of ultimately periodic sequences that are admissible. In the framework of graphs, this is related to the study of an automaton $\mathcal{G}'_\beta$, defined below, similarly generated as in Section 3.2 but where the sense of the edges are reverted.

In Section 4, we have constructed an automaton which recognizes finite or ultimately periodic expansions of 0 in base β which are defined on the alphabet $\mathcal{A}_\beta$. Since $\beta > 1$, non-finite expansions of 0 in base β

define formal power series in β that do not represent real numbers. However, when β is a Pisot number, we obtain well defined converging series if we replace β by any of its algebraic conjugates α_j. In the case of a ultimately periodic expansion, this can be done using the field morphism τ_j, since ultimately periodic expansions of 0 in base β characterize the elements of $\mathbb{Q}(\beta)$ in the Pisot case ([12, 42]). This is why we consider mainly ultimately periodic expansions from now on. We will see that the limit cases in the computation of $L_\oplus$ can be computed in an algorithmic way.

Assume now that β is a Pisot number of algebraic degree d. If we revert the sense of the edges in $\mathcal{G}$, the mirror image of $(u_i)_{i\in\mathbb{N}^*}$, where $(u_i)_{i\in\mathbb{N}^*}$ labels a path in $\mathcal{G}$, belongs to a compact subset of $\mathcal{A}_\beta^{\mathbb{N}^*}$. The sequence $(x_k)_{k\in\mathbb{N}^*}$ of elements of $\mathbb{R}^d$ defined by $p_{\mathcal{H}_j}(x_k) = \sum_{i=0}^{k} d_{i+1}\alpha_j^i$ is a sequence taking values in the Rauzy fractal $\mathcal{T}_\beta$. Moreover, since β is a Pisot number, $p_{\mathcal{H}_j}(x_k)$ admits a limit for any j. Since $\mathcal{T}_\beta$ is closed, any formal power series in β whose coefficients are the terms of a ultimately periodic sequence which belongs to $\mathcal{X}_\beta$ can be represented in $\mathbb{R}^{d-1}$ as an element which belongs to the associated Rauzy fractal $\mathcal{T}_\beta$.

In order to compute the limit cases, that is, the β-fractional parts of sums of two ultimately periodic formal power series in β whose coefficients satisfy the admissibility condition, we have to revert the edges in the construction of $\mathcal{G}$. We want here to obtain two-sided expansions of 0 with only finitely many non-zero terms to the right, whereas we studied in Section 3 two-sided expansions of 0 with only finitely many non-zero terms to the left. More precisely, since we revert the sense of reading, the algorithmic construction of the automaton $\mathcal{G}'$ is the following, with $V'_0 = \{0\}$:

$$\text{for all } n \in \mathbb{N}, V'_{n+1} = \Big(\bigcup_{k\in[\![-2\lfloor\beta\rfloor,\lfloor\beta\rfloor]\!]} f_k^{-1}(V'_n) \cap \mathbb{Z}^d \Big) \cap 3\mathcal{R}'_\beta. \tag{10}$$

Remark 5.1. *Note that β is a unit if and only if $f_i^{-1}(\mathbb{Z}^d) \subset \mathbb{Z}^d$ for any $i \in \mathbb{Z}$. In this case, the definition of V'_{n+1} in (10) does not require the presence of the intersection with $\mathbb{Z}^d$. This intersection is however needed in the non-unit case, since $f_{u_0}^{-1}(\mathbb{Z}^d) \subset \mathbb{Q}^d$ is not sufficient to deduce anything about the finiteness of the constructed automaton. We do not need to distinguish the two cases of a unit and a non-unit number in (7).*

The automaton $\mathcal{G}'$ can be pruned following the steps of reduction that are described in Section 4.1; we obtain in the same way a reduced automaton ${\mathcal{G}'}_\beta^+$. The loops of ${\mathcal{G}'}_\beta^+$ are exactly the loops of $\mathcal{G}_\beta^+$ labelled by the mirror image of admissible words $\overline{v}$, since the strongly connected component which contains $\{0\}$ in $\mathcal{G}$ does not change if we revert the sense of reading. However, since the sense of reading is significant in the definition of the connected component of $\mathcal{G}$ which contains $\{0\}$, there is no connection between the ultimately periodic paths in $\mathcal{G}_\beta^+$ and those in ${\mathcal{G}'}_\beta^+$. Then, we find the set of limit cases by finding the finite number of ultimately periodic paths in ${\mathcal{G}'}_\beta^+$, that can be done following the results described in Section 4. We detail in Section 5.3 the example of Tribonacci.

5.2 An effective construction of Thurston's automaton

We retrieve here the known result that a Pisot number is a Parry number, see [12, 42]. We give an algebraic construction of an automaton which is originally introduced by Thurston in [47].

We assume in this section that β is a Pisot number. As we have previously seen for the more general case of a Perron numbers of degree d, we can describe $\mathbb{R}^d$ as $\mathcal{D} \underset{j\in J}{\oplus} \mathcal{H}_j$. We recall that the map $\Phi : \mathcal{A}_\beta^{\mathbb{Z}} \to \mathbb{R}^d$ is defined as follows. For an admissible sequence $u = (u_i)_{i\in\mathbb{Z}}$, we have $p_{\mathcal{D}}(\Phi(u)) = -\sum_{i\in\mathbb{N}} u_i\beta^{-i}$, and $p_{\mathcal{H}_j}(\Phi(u)) = \sum_{i\in\mathbb{N}^*} u_i\alpha_j^i$ for all $j \in J$. Additionally, $\Phi \circ S(u) = f_{u_i} \circ \Phi(u)$ as we have seen in Lemma 3.1, and the coordinates of Φ are bounded both on $\mathcal{D}$ and on $\mathcal{H}_j$ for all $j \in J$. This implies that there exists a compact set $K \subset \mathbb{R}^d$ such that for any u, $\Phi(u) \in K$.

Let β be a Pisot number of degree d. Let $d_\beta(1) = (u_i)_{i\in\mathbb{N}^*}$. Let $v = (v_i)_{i\in\mathbb{N}^*}$ be the sequence defined by $v_1 = -1$ and $v_{i+1} = u_i$ for any $i \in \mathbb{N}^*$. The elements of $(\Phi(S^k(v)))_{k\in\mathbb{N}^*}$ are the images of 1 under finitely many maps $(f_i)_{i\in\mathcal{A}_\beta}$; there exists an infinite path $((s_i, s_{i+1}, v_i))_{i\in\mathbb{N}^*}$ in $\mathcal{G}$, with $s_i = \Phi(S^i(v))$ for any $i \in \mathbb{N}^*$. Since $\mathcal{G}_\beta^+$ is finite, there exist $n, p \in \mathbb{N}$ such that $s_n = s_{n+p}$. However, since $d_\beta(1) = (u_i)_{i\in\mathbb{N}^*}$,

$(u_{i+k})_{i\in\mathbb{N}^*}$ is admissible for any $k \in \mathbb{N}$. Due to Proposition 3.8, one gets $p_{\mathcal{D}}(s_{i+1}) = T_\beta^i(1)$ for all $i \in \mathbb{N}^*$. This implies that $T^n(1) = T^{n+p}(1)$. Hence $(u_i)_{i\in\mathbb{N}^*}$ is ultimately periodic, that is, β is a Parry number.

5.3 Construction of $\mathcal{G}'^+_\beta$ in the case of Tribonacci

Let us recall that the Tribonacci numeration system, introduced in Example 2.6, is defined by the positive root of the polynomial $X^3 - X^2 - X - 1$. The finiteness property holds for this number system; as a consequence, the connected component of $\mathcal{G}^+_\beta$ which contains the state $\{0\}$ is strongly connected, and $\mathcal{G}'^+_\beta$ admits $\mathcal{G}^+_\beta$ as a subgraph. Figure 5 represents the associated graph $\mathcal{G}'^+_\beta$.

There exists a ultimately periodic path in $\mathcal{G}'^+_\beta$ which starts from the state $\{0\}$ and reaches the state $\{0.100011\}$. However, the state $\{0.100011\}$ does not belong to the strong connected component of $\mathcal{G}'^+_\beta$ which contains the state $\{0\}$. Let us give an interpretation of this fact. The two-sided sequence $^\infty(11(-2))100011.0^\infty$ is an expansion of 0 in base α_j, although the sum is not defined in base β, and it belongs to $\mathcal{X}'_\beta$. Indeed, there exists a loop of length 3 in $\mathcal{G}'^+_\beta$ which is labelled by the word $11(-2) \in \mathcal{L}'_\beta$; the states of this loops, among which $\{\beta^{-1}+\beta^{-5}+\beta^{-6}\}$, do not belong to the strongly connected component of $\mathcal{G}^+_\beta$ which contains the state $\{0\}$. We deduce that the real number $z = \beta^{-1}+\beta^{-5}+\beta^{-6}$ is a limit case: it cannot be the β-fractional part of the sum of two β-integers, however there exist two elements x and y, which belong in fact to the boundary of the associated Rauzy fractal, such that, among the possible α_j-expansions of their sum, one of them admits $\tau_j(z) = \alpha_j^{-1}+\alpha_j^{-5}+\alpha_j^{-6}$ as its α_j-fractional part. We check that, if we take $x = y = \frac{1}{1-\alpha^3}$, then x belongs to $\mathcal{T}_\beta$, and $x+x$ admits three different α_j-expansions; among these α_j-expansions, one of them admits 100011 as its α_j-fractional part. See [11] for more details.

If we remove the states $\{0.0011\}$, $\{0.00011\}$, $\{0.100011\}$ and $\{-0.10101\}$ in $\mathcal{G}'^+_\beta$, we check that the remaining graph is strongly connected, that is, we obtain $\mathcal{G}^+_\beta$. The states s such that $p_{\mathcal{D}}(s) \geq 0$ define the possible β-fractional parts of the sum of two positive β-integers, which are:

$$\{0, \beta^{-1}, \beta^{-2}, \beta^{-1}+\beta^{-2}, \beta^{-3}, \beta^{-1}+\beta^{-3}, \beta^{-2}+\beta^{-3}, \beta^{-1}+\beta^{-3}, \beta^{-2}+\beta^{-4}, \beta^{-1}+\beta^{-3}+\beta^{-5}\}.$$

We obtain thanks to a similar computation the set of β-fractional parts of the difference of two positive β-integers. Note that, for any vertex of $\mathcal{G}'^+_\beta$ or $\mathcal{G}^+_\beta$, there exists an infinite loop using this vertex starting from the state $\{0\}$, but the edge having for initial state $\{-\beta\}$ and for final state $\{-1-\beta^{-1}\}$ cannot be used in any infinite loop starting from the state $\{0\}$.

Remark 5.2. *Similarly to what happens for the state $\{\beta^{-1}+\beta^{-5}+\beta^{-6}\}$, the state $\{-\beta^{-1}-\beta^{-3}-\beta^{-5}\}$ belongs to $\mathcal{G}'^+_\beta$, but it does not belong to $\mathcal{G}^+_\beta$. This means that $\beta^{-1}+\beta^{-3}+\beta^{-5}$ cannot be the β-fractional part of the difference of two positive integers. However there exists $(x, y) \in \mathcal{T}^2$ such that, among the α-expansions of $x - y$, one of them has 0.10101 as its α-fractional part. By computation, we find that, when $x = \frac{1+\alpha}{1-\alpha^3}$ and $y = \frac{\alpha^2}{1-\alpha^3}$, then $(x, y) \in \mathcal{T}^2$ and $x - y = y + \alpha^{-1} + \alpha^{-3} + \alpha^{-5}$.*

Acknowledgements

I am indebted to Pierre Arnoux and Valérie Berthé for their advices and corrections, and to Anne Siegel and Christiane Frougny for many interesting remarks and comments. I warmly thank the referees for their corrections and suggestions.
