### Primes and squares with preassigned digits

### **Cathy Swaenepoel**

IMJ-PRG, Université Paris Cité.

32èmes Journées Arithmétiques, Nancy, July 3, 2023.

Representation of an integer  $k \in [0, g^n]$  in base  $g \ge 2$ :

$$k = \sum_{j=0}^{n-1} \varepsilon_j(k) g^j.$$

where  $\varepsilon_j(k) \in \{0, \ldots, g-1\}$  is the **digit** of k at the position j.

## Integers with preassigned digits

- $A \subset \{0, \ldots, n-1\}$ : set of positions,
- $d = (d_j)_{j \in A}$ : preassigned digits at these positions.

$$|\underbrace{\{k < g^n : \forall j \in A, \varepsilon_j(k) = d_j\}}_{\substack{\text{sparse set} \\ \text{if } |A| \to +\infty \text{ as } n \to +\infty}}| = g^{n-|A|}$$

## Prime numbers with preassigned digits

 $\text{Goal: estimate } |\{p < g^n : \forall j \in A, \, \varepsilon_j(p) = d_j\}| \text{ as } n \to +\infty.$ 

- Kátai (1986).
- Wolke (2005): asymptotic,  $|A| \leq 2$  $(|A| \leq (1 - \varepsilon)\sqrt{n}$  under GRH).
- Harman (2006): lower bound,  $|A| \leq \text{constant}$ .
- Harman-Kátai (2008): asymptotic,  $|A| \ll \sqrt{n} (\log n)^{-1}$ .
- Bourgain (2013): asymptotic,  $|A| \ll n^{4/7} (\log n)^{-4/7}$ , in base 2.
- Bourgain (2015): asymptotic,  $|A| \leq cn$ , in base 2 (c > 0 absolute constant).

### Theorem 1 (S. 2020)

For any  $g \ge 2$ , there exist an explicit  $c = c(g) \in ]0, 1[$  and  $\delta = \delta(g) > 0$  such that for any  $n \ge 1$ , for any  $A \subset \{0, \ldots, n-1\}$  satisfying  $\{0, n-1\} \subset A$  and

 $|A| \leqslant cn,$ 

for any  $(d_j)_{j \in A} \in \{0, \dots, g-1\}^A$  such that  $(d_0, g) = 1$  and  $d_{n-1} \ge 1$ , we have  $|\{p < g^n : \forall j \in \mathbf{A}, \varepsilon_j(p) = d_j\}| = \frac{g^{n-|\mathbf{A}|}}{\log a^n} \frac{g}{\varphi(a)} \left(1 + O_g\left(n^{-\delta}\right)\right).$ 

This generalizes Bourgain's result (2015) to any base.

Theorem 1 holds with c(g) given by

| g                | 2    | 3    | 4    | 5    | 10   | $10^{3}$ | $2^{200}$ |
|------------------|------|------|------|------|------|----------|-----------|
| $c(g)\cdot 10^2$ | 0.21 | 0.31 | 0.36 | 0.40 | 0.47 | 0.68     | 0.90      |

# Squares with preassigned digits

Denote  $S = \{\ell^2, \ell \ge 0\}$  the set of squares.

 $\text{Goal: estimate } |\mathcal{S} \cap \{k < g^n : \forall j \in \mathcal{A}, \, \varepsilon_j(k) = d_j\}| \text{ as } n \to +\infty.$ 

• Squares are a priori easier to handle than primes (distribution in short intervals, in arithmetic progressions, ...).

But

- squares are sparser than primes,
- there are algebraic constraints on the digits of squares.

 $\rightarrow$  New difficulties for squares.

 $v_2(g) = 2$ -adic valuation of g.

• If g is odd or  $v_2(g) \ge 3$ ,

$$\mathcal{H}(g): \{0\} \subset A, (d_0, g) = 1, d_0 \text{ square mod } g.$$

• If  $v_2(g) = 2$ ,

$$\mathcal{H}(g): \quad \{0,1\} \subset A, \, (d_0,g)=1, \, d_1g+d_0 \, \, {
m square \, mod} \, \, g^2.$$

• If  $v_2(g) = 1$  (e.g. g = 2 or g = 10),

 $\mathcal{H}(g): \quad \{0,1,2\} \subset A, \, (d_0,g) = 1, \, d_2g^2 + d_1g + d_0 \, \, \text{square mod} \, \, g^3.$ 

#### Theorem 2 (S. 2023+)

For any  $g \ge 2$ , there exist an explicit  $c = c(g) \in ]0, 1/2[$  and  $\delta = \delta(g) > 0$  such that for any  $n \ge 3$ , for any  $A \subset \{0, \ldots, n-1\}$  and  $d = (d_j)_{j \in A} \in \{0, \ldots, g-1\}^A$  satisfying  $\mathcal{H}(g)$ ,  $n - 1 \in A$ ,  $d_{n-1} \ge 1$  and

 $|A| \leqslant cn,$ 

we have

$$|\mathcal{S} \cap \{k < g^n : \forall j \in \boldsymbol{A}, \, \varepsilon_j(k) = \boldsymbol{d_j}\}| = \mathfrak{S}(g, n, \boldsymbol{A}, \boldsymbol{d}) \left(1 + O_g\left(n^{-\delta}\right)\right)$$

where

$$\mathfrak{S}(g,n,\pmb{A},\pmb{d}) = \sum_{\substack{k < g^n \\ \forall j \in \pmb{A}, \, \varepsilon_j(k) = \pmb{d}_j}} \frac{\eta(g)}{2\sqrt{k}}, \quad \eta(g) = \left\{ \begin{array}{cc} 2^{\omega(g)}, & g \text{ odd}, \\ 2^{\omega(g)+1}, & g \text{ even} \end{array} \right.$$

In particular, the order of magnitude of  $|S \cap \{k < g^n : \forall j \in A, \varepsilon_j(k) = d_j\}|$  is  $g^{\frac{n}{2} - |A|}$ .

Theorem 2 holds with c(g) given by

| g                | 2   | 3   | 4   | 5   | 10  | 16  | $2^{32}$ | $2^{64}$ |
|------------------|-----|-----|-----|-----|-----|-----|----------|----------|
| $c(g)\cdot 10^2$ | 0.5 | 0.9 | 1.1 | 1.3 | 1.6 | 1.8 | 3.6      | 4        |

An example where  $(d_0, g) > 1$   $(g = 10, d_0 = 5)$ 

#### Lemma (S.)

Let m such that  $\frac{n}{4} - m \to +\infty$  as  $n \to +\infty$ . Choose

$$A = \{0, 2, 4, \dots, 2(m-1), n-1\}.$$

Let s such that  $s \equiv 1 \mod 8$  and  $s \equiv 0 \mod 5^{2m-1}$  and let  $d \in \{0, \dots, 9\}$ . Choose

$$d_{2i} = \varepsilon_{2i}(s)$$
 for  $i = 0, \dots, m-1, \quad d_{n-1} = d.$ 

Then we have

$$S \cap \{k < 10^n : \forall j \in A, \, \varepsilon_j(k) = d_j\} = \frac{C(d)}{2^{|A|}} \, 10^{\frac{n}{2} - |A|} \, (1 + o(1))$$

where C(d) > 0 depends only on d.

So the order of magnitude may be smaller than  $10^{\frac{n}{2}-|A|}$ .

Idea: at the positions  $1, 3, \ldots, 2m-3$ , the digits of k have to be the digits of s.

Cathy Swaenepoel

### Notations for the proof of Theorem 2

• 
$$e(x) = \exp(2i\pi x), x \in \mathbb{R}.$$

• 
$$\mathcal{S} = \{\ell^2, \, \ell \ge 0\}$$
 the set of squares.

• 
$$\mathcal{D}(n, A, \mathbf{d}) = \{k < g^n : \forall j \in A, \, \varepsilon_j(k) = d_j\}.$$

• 
$$N = g^n$$
.

We want to estimate

$$\sum_{N_0 \leqslant k < N_1} \mathbf{1}_{\mathcal{S}}(k) \mathbf{1}_{\mathcal{D}(n,A,d)}(k)$$

where  $N_0 = d_{n-1}g^{n-1}$  and  $N_1 = (d_{n-1} + 1)g^{n-1}$ .

### Method

Use the circle method:

$$\sum_{N_0 \leqslant k < N_1} \mathbf{1}_{\mathcal{S}}(k) \mathbf{1}_{\mathcal{D}(n,A,d)}(k) = \int_0^1 S(\alpha) \overline{R(\alpha)} d\alpha$$

where

$$S(\alpha) = \sum_{\substack{N_0 \leqslant k < N_1 \\ \text{can be large only when } \alpha \text{ is close to} \\ \text{a rational with small denominator} \\ \text{i.e. } \alpha \text{ is in a major arc}} \quad \text{and} \quad \underbrace{R(\alpha) = \sum_{\substack{N_0 \leqslant k < N_1 \\ \text{depends on the digital conditions}}}_{\text{depends on the digital conditions}} \cdot \underbrace{R(\alpha) = \sum_{\substack{N_0 \leqslant k < N_1 \\ \text{depends on the digital conditions}}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot \underbrace{\mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) \, .}_{\text{depends on the digital conditions}} \cdot$$

- integral over major arcs  $\rightarrow$  main term (+ error term)
- integral over minor arcs  $\rightarrow$  error term

# Fourier transform of $\mathbf{1}_{\mathcal{D}(n, A, d)}$

$$F_n(\alpha) = \frac{1}{g^{n-|A|}} \sum_{k < g^n} \mathbf{1}_{\mathcal{D}(n,A,d)}(k) \, \mathbf{e}(k\alpha) = \frac{1}{g^{n-|A|}} R(\alpha).$$

By writing k in base g, we obtain:

$$|F_n(\alpha)| = \prod_{\substack{0 \le j \le n-1 \\ j \notin A}} \frac{\Phi_g\left(g^j \alpha\right)}{g} \qquad \text{where } \Phi_g(t) = \left|\sum_{v=0}^{g-1} \mathbf{e}(vt)\right| = \left|\frac{\sin \pi gt}{\sin \pi t}\right|.$$

For 
$$g = 2$$
,  

$$|F_n(\alpha)| = \prod_{\substack{0 \leq j \leq n-1 \\ j \notin A}} |\cos \pi 2^j \alpha|.$$

We need very strong upper bounds for  $||F_n||_1$  and some (weighted) averages of  $|F_n(a/q)|$ .

$$\int_{\mathfrak{m}} \left| S(\alpha) \overline{R(\alpha)} \right| d\alpha = g^{n-|A|} \int_{\mathfrak{m}} \left| S(\alpha) \overline{F_n(\alpha)} \right| d\alpha \leqslant g^{n-|A|} \left\| F_n \right\|_1 \sup_{\alpha \in \mathfrak{m}} \left| S(\alpha) \right|$$

• Use the strong upper bound:

$$\|F_n\|_1 \ll N^{\xi-1} \log N \qquad (\text{trivial: 1})$$

where  $\xi$  is explicit and  $\xi \to 0$  as  $|A|/n \to 0$ .

 $\bullet$  Use a classical estimate on Weyl sums to bound  $|S(\alpha)|$  over the minor arcs:

$$\sup_{\alpha \in \mathfrak{m}} |S(\alpha)| = \sup_{\alpha \in \mathfrak{m}} \left| \sum_{\sqrt{N_0} \leqslant \ell < \sqrt{N_1}} e(\ell^2 \alpha) \right| \ll \frac{\sqrt{N}}{\sqrt{B_1}} \qquad \text{(trivial: } \sqrt{N}\text{)}$$
 where  $B_1$  is a small power of  $N$ .

## Contribution of all major arcs around a/q, q fixed

Up to an admissible error, the contribution of all major arcs around a/q (q fixed) is

$$\mathcal{C}(q) := \sum_{N_0 \leqslant k < N_1} \frac{\mathbf{1}_{\mathcal{D}(n,A,d)}(k)}{2\sqrt{k}} H(q,k)$$

where

$$H(q,k) = \frac{1}{q} \sum_{\substack{1 \leqslant a \leqslant q \\ (a,q) = 1}} G(q,a) e\left(\frac{-ka}{q}\right) \quad \text{ and } \quad G(q,a) = \sum_{u=1}^{q} e\left(\frac{au^2}{q}\right).$$

•  $q \mapsto H(q,k)$  is multiplicative, simple formulas for  $H(p^{\nu},k).$ 

- Write q = sq' where  $(p \mid s \Rightarrow p \mid g)$  and (q', g) = 1.
- Distinguish two cases depending on s and q'.
  - In one case, C(q) is large  $\rightarrow$  main term.
  - In the other case,  $\mathcal{C}(q)$  is small ightarrow error term

(use a strong bound for the Fourier transform of  $\mathbf{1}_{\mathcal{D}(n,A,d)}$ ).

## Conclusion of the proof

Taking  $\boldsymbol{c}$  sufficiently small, we get

$$\sum_{k < g^n} \mathbf{1}_{\mathcal{S}}(k) \mathbf{1}_{\mathcal{D}(n,A,d)}(k) = \mathfrak{S}(g,n,A,d) \left( 1 + O_g \left( n^{-\delta} \right) \right)$$

for some  $\delta>0,$  where

$$\mathfrak{S}(g,n,A,\boldsymbol{d}) = \sum_{\substack{k < g^n \\ \forall j \in A, \, \varepsilon_j(k) = d_j}} \frac{\eta(g)}{2\sqrt{k}}, \quad \eta(g) = \left\{ \begin{array}{ll} 2^{\omega(g)}, & g \text{ odd}, \\ 2^{\omega(g)+1}, & g \text{ even}. \end{array} \right.$$

The main term comes from the major arcs around a/q with

- $q \in \{1, p\}$  if g is a prime  $p \ge 3$ ,
- $q \in \{1, 4, 8\}$  if g = 2,

• 
$$q \in \{1, 4, 5, 8, 20, 40\}$$
 if  $g = 10$ .

- In any base  $g \ge 2$ , we obtain an asymptotic formula for the number of primes and squares with a positive proportion of preassigned digits.
- We give explicit values for the proportion of digits this method allows us to preassign.

- In any base g ≥ 2, we obtain an asymptotic formula for the number of primes and squares with a positive proportion of preassigned digits.
- We give explicit values for the proportion of digits this method allows us to preassign.

Thank you for your attention!
