Introduction and motivation

Polynomials in $\mathbb{Z}[x]$ with only rational roots are the simplest examples of decomposable polynomials and forms. Such polynomials play an important role in the theory of Diophantine equations. (See e.g. results of **Evertse and Győry**.)

There is also an extensive literature on polynomials with restricted coefficients, in particular, with coefficients belonging to one of the sets $\{-1, 1\}, \{0, 1\}$ or $\{-1, 0, 1\}$. (See e.g. results concerning Littlewood polynomials and Newman polynomials.)

The set of polynomials $f(x) \in \mathbb{Z}[x]$ with all coefficients in $\{-1, 0, 1\}$, constant term non-zero and only rational roots is very restricted. The degree of *f* is at most 3, an example is

$$f(x) = x^3 - x^2 - x + 1 = (x - 1)^2(x + 1).$$

< 日 > < 同 > < 回 > < 回 > < 回 > <

Theorem 1 (Tijdeman, Varga, H. (202?))

Let $f(x) \in \mathbb{Z}[x]$ be a polynomial of degree n with only non-zero rational roots and height bounded by $H \ge 2$. Then we have both

$$n \leq \left(\frac{2}{\log 2} + o(1)\right) \log H \quad (H \to \infty)$$
 (1)

and

$$n \le \frac{5}{\log 2} \log H. \tag{2}$$

Further, the constants $2/\log 2$ and $5/\log 2$ in (1) and (2), respectively, are best possible.

Remarks. For any $f \in \mathbb{Z}[x]$ of degree *n*, the height of $g := x^m f(x)$ is the same as that of *f*, while deg(g) = m + n. So the assumption that the roots of *f* are non-zero is clearly necessary.

Several authors have considered upper bounds for the number *r* of real roots of $f(x) \in \mathbb{R}[x]$. (See e.g. results of **Bloch and Pólya**, **E. Schmidt**, **Schur**, **Erdős and Turán**, **Littlewood and Offord**, **Borwein**, **Erdélyi and Kós**.)

For example, a result of **Schur** implies for polynomials $f(x) \in \mathbb{Z}[x]$ with only real roots that

$$n \leq (4 + o(1)) \log H \quad (H \to \infty).$$

Proof of Theorem 1

On the one hand, let $f(x) = \sum_{j=0}^{n} a_j x^j$. Then

$$|f(\mathbf{i})| \leq \left| \sum_{j \text{ is even}} |\mathbf{a}_j| + \mathbf{i} \sum_{j \text{ is odd}} |\mathbf{a}_j| \right| \leq \sqrt{\frac{1}{2}n^2 + n + 1} H.$$
(3)

On the other hand, we may write $f(x) = \prod_{j=1}^{n} (q_j x - p_j)$ with $p_j, q_j \in \mathbb{Z}_{\neq 0}$ for all *j*. Then

$$|f(\mathbf{i})| = \left| \prod_{j=1}^{n} (q_j \mathbf{i} - p_j) \right| = \prod_{j=1}^{n} \sqrt{q_j^2 + p_j^2} \ge (\sqrt{2})^n.$$
(4)

Therefore,

$$n\log 2 \le \log\left(\frac{1}{2}n^2 + n + 1\right) + 2\log H. \tag{5}$$

From this (1) easily follows.

イロト 不得 トイヨト イヨト

Proof of Theorem 1

For the height *H* of the polynomial $f(x) = (x^2 - 1)^{n/2}$ with even $n \ge 2$ by Stirling's formula we have $\log H = (1 + o(1))n \log 2/2$. This shows that the constant $2/\log 2$ in (1) is best possible.

To prove (2), observe that assuming $(5/\log 2) \log H < n$ from (5) we obtain

$$n\log 2 < \log\left(\frac{1}{2}n^2 + n + 1\right) + \frac{2n\log 2}{5},$$

whence $n \leq 9$.

These cases can be checked relatively easily, and (2) holds. In particular, the polynomial

$$(x-1)^3(x+1)^2 = x^5 - x^4 - 2x^3 + 2x^2 + x - 1$$

shows that the constant $5/\log 2$ in (2) is best possible.

Theorem 2 (Tijdeman, Varga, H. (202?))

Every polynomial $f(x) \in \mathbb{Z}[x]$ with only rational roots of which no coefficient is divisible by 2 or 3 has degree at most 3.

The example

$$f(x) = x^3 - x^2 - x + 1 = (x - 1)^2(x + 1)$$

shows that degree 3 is possible.

A B F A B F

< 4 →

Background of the proof of Theorem 2

The proof is based upon the following two lemmas.

Lemma 1 (Fine (1947))

Let n be a positive integer such that all the coefficients of $(x + 1)^n$ are odd. Then n is of the shape $2^{\alpha} - 1$ with some $\alpha \in \mathbb{Z}_{\geq 0}$.

Lemma 2 (Tijdeman, Varga, H. (202?))

Let a, b be non-negative integers. Put n := a + b. If none of the coefficients of $(x - 1)^a (x + 1)^b$ is divisible by 3, then n is of the shape $3^{\beta} - 1, 2 \cdot 3^{\beta} - 1, 3^{\gamma} + 3^{\delta} - 1$ or $2 \cdot 3^{\gamma} + 3^{\delta} - 1$ with $\beta \ge 0, \gamma > \delta \ge 0$.

Remark. For all the mentioned values in Lemma 2 there are polynomials without coefficients divisible by 3.

L. Hajdu (University of Debrecen)

Polynomials with only rational roots

We may assume that *f* is monic.

Since the roots of *f* are odd, Lemma 1 shows that n + 1 is a power of 2.

Further, since the roots of *f* are not divisible by 3, by Lemma 2 we get that n + 1 is of the shape $3^{\beta}, 2 \cdot 3^{\beta}, 3^{\gamma} + 3^{\delta}$ or $2 \cdot 3^{\gamma} + 3^{\delta}$.

The combination is possible only for n = 0, 1, 3.

Polynomials with coeffs having only prime factors coming from a fixed finite set

Theorem 3 (Tijdeman, Varga, H. (202?))

Let *S* be a finite set of primes with |S| = s and *n* a positive integer.

There exists an explicitly computable constant C = C(n, s) depending only on n and s and sets T_1, T_2 with $\max(|T_1|, |T_2|) \le C$ of n-tuples of S-units and (n-1)/2-tuples of S-units for n odd, respectively, such that if f(x) is an S-polynomial of degree n having only rational roots q_1, \ldots, q_n , then q_1, \ldots, q_n satisfy one of the conditions (i) or (ii): (i) $(q_1, \ldots, q_n) = u(r_1, \ldots, r_n)$ with some $(r_1, \ldots, r_n) \in T_1$ and S-unit

И,

(ii) n = 2t + 1 is odd, and re-indexing q_1, \ldots, q_n if necessary, we have $q_1 = u$ and $(q_2, \ldots, q_n) = v(r_1, -r_1, \ldots, r_t, -r_t)$ with some $(r_1, \ldots, r_t) \in T_2$ and S-units u, v.

Further, the possibilities (i) and (ii) cannot be excluded.

Background of the proof of Theorem 3

We use the theory of *S*-unit equations. Let *S* be a finite set of primes, b_1, \ldots, b_m non-zero rationals, and consider the equation

$$b_1x_1 + \cdots + b_mx_m = 0$$
 in S-units x_1, \ldots, x_m . (6)

A solution (y_1, \ldots, y_m) of (6) is called non-degenerate if

$$\sum_{i \in I} b_i y_i \neq 0 \text{ for each non-empty subset } I \text{ of } \{1, \dots, m\}.$$

Two solutions (y_1, \ldots, y_m) and (z_1, \ldots, z_m) are called proportional, if there is an *S*-unit *u* such that $(z_1, \ldots, z_m) = u(y_1, \ldots, y_m)$.

Lemma 3 (Amoroso and Viada (2009))

Equation (6) has at most $(8m - 8)^{4(m-1)^4(m+s)}$ non-degenerate, non-proportional solutions, where s = |S|.

L. Hajdu (University of Debrecen)

Write $f(x) = \sum_{j=0}^{n} a_j x^j$, having only rational roots q_1, \ldots, q_n .

By our assumption, a_0, a_1, \ldots, a_n are integral *S*-units.

We have

$$A_j = \sigma_j(q_1, \ldots, q_n) \quad (1 \le j \le n)$$

where $A_j = (-1)^j a_{n-j}/a_n$ and σ_j is the *j*-th elementary symmetric polynomial (of degree *j*) of q_1, \ldots, q_n .

This is a system of S-unit equations, which by a careful analysis, with delicate considerations lead to the statement by Lemma 3.

Finally, we show that the possibilities (i) and (ii) cannot be excluded.

If r_1, \ldots, r_n is a set of rational roots of an *S*-polynomial of degree *n*, then clearly, the same is true for ur_1, \ldots, ur_n for any *S*-unit *u*, showing the necessity of (i).

On the other hand, let r_1^2, \ldots, r_t^2 be the rational roots of the *S*-polynomial $(x - r_1^2) \cdots (x - r_t^2)$. Then in the polynomial $(x^2 - r_1^2) \cdots (x^2 - r_t^2)$, all the coefficients of the even powers of *x* are *S*-units (while the coefficients of the odd powers of *x* equal 0). Thus for any *S*-units *u*, *v*, all the coefficients of the polynomial

$$(x+u)(x-vr_1)(x+vr_1)\cdots(x-vr_t)(x+vr_t)$$

are S-units. This shows that (ii) cannot be excluded either.

< 日 > < 同 > < 回 > < 回 > < 回 > <

Problem 1. Is it true that for any primes p and q there exists an $n_1 = n_1(p,q)$ such that every polynomial $f(x) \in \mathbb{Z}[x]$ with only rational roots of which no coefficient is divisible by p or q has degree at most n_1 ?

Theorem 2 shows that the answer is 'yes' for the pair of primes (p,q) = (2,3).

A weaker statement is a restriction to *S*-polynomials.

Problem 2. Is it true that for any finite set *S* of primes there exists an $n_2 = n_2(S)$ such that every *S*-polynomial $f(x) \in \mathbb{Z}[x]$ with only rational roots has degree at most n_2 ?

Theorem 2 yields an affirmative answer for sets S of primes with 2, $3 \notin S$.

The last problem is raised by Lemmas 1 and 2.

Problem 3. Is it true that for every prime p there exists a constant c(p) such that if $f(x) \in \mathbb{Z}[x]$ has only rational roots and none of the coefficients of f is divisible by p, then $\deg(f) + 1$ in its p-adic expansion has at most c(p) non-zero digits? In particular, can one take c(p) = p - 1?

Lemmas 1 and 2 show that the answer is 'yes' with c(p) = p - 1 for p = 2, 3. Note that an affirmative answer to Problem 3 through a deep result of **Stewart** would yield positive answers to Problems 1 and 2, as well.

Thank you very much for your attention!

A .
